All supervisors' plans are operated on an individual basis, each foreman participating only in the results obtained in the department over which he has control. This type of arrangement makes it possible to have reported all those items of trouble existing in certain departments caused by some other department. A foreman will not allow trouble caused in a preceding department to reduce his premium. The trouble is reported and investigated by people in a position to give this unbiased attention. If the complaint is justified, the increased costs entailed in the one department are transferred to the department causing this trouble, thereby affecting the premium of that department's foreman.

The amount of business the company does affects the supervisor's premium indirectly in that it is not always possible to reduce indirect labor costs in exactly the same proportion as a reduction in the amount of business done. It is also possible when the amount of business increases for the foreman to receive some slight advantage by avoiding the increase of indirect labor costs when direct labor pay rolls increase. On the other hand, when direct labor pay rolls decrease, the reduction of forces is usually effected by the elimination of the undesirable and the poor people in the department. This process raises the average productivity of the department and has a tendency to offset the decrease in premium on the indirect labor factor. It has been our contention that the foreman's premium should be dependent upon efficiency only. The size of the department under the direction of the foreman shall be reflected in the basic salary. Any changes in the size of the department are taken care of by changes in salary.

The standards upon which the foreman's premiums are based are permanent in exactly the same manner as all standard time units employed for wage incentive plans for direct workers.

Premiums earned by supervisors are not secret in this company. Great use is made of the records of good premiums earned by satisfactory supervisors as examples to foremen whose departments are temporarily in poor shape. The results obtained from the operation of incentives in the Hole-proof Hosiery Company are as follows:

- a. Indirect labor costs are lower.
- b. Efficiency is higher.

- c. Quality is better.
- d. New styles get underway faster through rapid standardization of work.
- e. Waste has been materially reduced by those participating under these plans.

Many other intangible results have been obtained, one of the outstanding of which has been the improved attitude of all foremen. They have assumed generally a businesslike attitude towards premiums and have learned that business is a game of rendering universally satisfactory service involving sportsmanship as well as judgment and resourcefulness.

SETTING THE BEGINNING WAGE FOR JOBS ON INCENTIVE WAGE PAYMENT PLANS

By E. H. LITTLE, *Assistant Supervisor, Industrial Relations, United States Rubber Company*

There are certain principles to be observed in setting the beginning rates of pay. These apply to the hiring rate and to the weekly wage until the payment for the individual's output exceeds the hiring rate.

Hiring Rates for Inexperienced Employees. There should be established one hiring rate for inexperienced employees for each class of labor. These hiring rates may fluctuate with changing labor conditions:

- A man's hiring rate.
- A woman's hiring rate.
- A young man's or a boy's hiring rate.

Exceptions. Certain unusual jobs for which particular qualifications are specified may require hiring rates higher than the one established for that class of labor. For the ordinary jobs, however, one hiring rate for each should be sufficient.

Fixing the Hiring Rate. The initial hourly rate should be as low as is consistent with the market hiring rate. It should be high enough to be competitive, but low enough so that the effort necessary to exceed that rate on the incentive wage payment plan presents as small a discouragement factor as possible.

When to Pay Day Work. If it takes two weeks or less to exceed the hiring rate on incentive wage payment, day work should be paid for this period on the theory that the cost of administering a training allowance would be greater than the benefit derived for so short a period.

Length of the Day Work Period. The length of the day work period should be the time that it is felt that all emphasis should be on quality and method of operation as compared to production. This period is usually one week and rarely exceeds two.

Training Allowance (or Training Bonus). After this period, day work payment should be supplemented by a training allowance. This allowance should decrease in proportion to the rate of normal increase of the average employee.

The Purpose of the Training Allowance. The aim of the training allowance is to provide production incentive as soon as possible. The allowance must be carefully adjusted to give a gradually ascending scale of pay, and closely followed to determine real reasons for individual variations from standard progress records.

How to Arrive at the Training Allowance. There should be a predetermined schedule of work for each job being learned, figured on the basis of progress records of average employees learning the job. This production should be paid for on an incentive wage payment basis. The difference between this amount and the amount guaranteed, figured daily, weekly, or hourly should be paid for on an hourly basis. This is the *training allowance*. If over four weeks are required by the average employee to earn more on an incentive wage payment than the hiring rate, the training allowance should be worked out so that the earnings of the average operator at the end of six weeks are at least two cents per hour above the hiring rate. Such a rate of increase should continue through the training period.

Hiring rate44 per hour Standard wage for job60 per hour				The exceptional operator	
Schedule, weeks	Training allowance	Predetermined estimate of earnings*	Predetermined estimate total earnings, average operators	Actual earnings	Actual total earnings
1st10	.44 day work	.15	44 day work
2d	28	16	.44	.22	50
3d	20	25	.45	.30	50
4th	17	.30	.47	.35	52
5th	12	35	.47	.41	53
6th	08	.40	.48	.47	55
7th04	.45	.49	.53	57
8th		50	50 { incentive wage payment	.60	60 { incentive wage payment

* NOTE. Based on progress record of actual earnings of ordinary employees who have learned the job.

Fixed Training Allowance vs. Percentage Training Allowance. By the above method the training allowance is fixed. Where a training allowance is on a percentage basis, the employee is paid actual earnings plus a predetermined percentage of estimated earnings. If the foregoing training allowance had been on this basis we should have had:

1st week, day work.

2d week, actual earnings plus 165 per cent of actual earnings.

3d week, actual earnings plus	80 per cent of actual earnings.
4th week, actual earnings plus	57 per cent of actual earnings.
5th week, actual earnings plus	34 per cent of actual earnings.
6th week, actual earnings plus	20 per cent of actual earnings.
7th week, actual earnings plus	9 per cent of actual earnings.

Training allowances are most needed for the average operator. If all operators were exceptional we could pay them on day work throughout the training period. A percentage training allowance unnecessarily rewards the operator who learns quickly and may prove to be a discouragement factor to the average or below average operator. Using these percentages to figure earnings of the exceptional operator in the foregoing table will illustrate the difference between a fixed and a percentage training allowance.

The Flexibility of Training Allowances. Training allowances, unlike rates, need not be fixed. They can be changed with each new group learning as well as with experience and changing conditions. Reductions in training allowances are no problem. Therefore since earnings less than the hiring rate during the learning period are very discouraging and consequently conducive to turnover, it is wise to err on the side of liberality in setting the training allowance. An average employee should never earn less per hour than his hiring rate.

CHAPTER X

QUALITY AND INSPECTION

BY ROBERT W. KENT, *Vice President, Bigelow, Kent, Willard & Co.*

The control of quality is the usually attributed reason for having inspection. When one gives even preliminary consideration to a non-dictionary definition of the term "inspection," it is not easy to comprehend why the term inspection should so generally be limited to a product. After all, inspection is investigation for the purpose of determining whether or not things are as they should be. Unfortunately, industry in general, and the public at large seem more frequently to believe that inspection is for the purpose of determining how large a proportion of things investigated may be found to be defective, or in other words, as they should not be.

It is probable that the majority of us when confronted with the term inspection or inspector think of a grouchy individual with a hammer and a stamping die, the latter of which he guards most zealously because its use constitutes approval. We think of this individual as being extremely niggardly and unwilling to approve anything that may by any possible chance be construed as not up to specification.

Fortunately, inspection as thus described represents but an infinitesimal amount of inspection as actually practiced.

Management is probably responsible 99 per cent of the time for success or failure in our various industrial enterprises. Unfortunately, in the great majority of cases management expends a large proportion of its time in inspection, or in other words, searching out the truth with regard to the operation of the business and the reason for these truths. When we find an enterprise in which management is not burdened with the responsibilities of investigation or inspection, but is able to devote a large proportion of its time to constructive effort in developing and applying cures and remedies for the unsatisfactory situations found as a result of investigation or inspection, then we may be assured of a highly successful enterprise.

Is it not reasonable, therefore, to assume that management's effort should be devoted as largely as possible to action rather than to investigation? The unsuccessful manager usually fails because of something he did *not* know rather than because of failure to act as a result of the things he did know.

When we assume that inspection applies only to the control of quality we are indeed overlooking a majority of the advantages that should be gained from inspection.

Uses of Inspection. In addition to control of quality, inspection can relieve management of much of its work of an investigating character. We

are told that inspection is for the purpose of quality control. Should it not also be for the purpose of cost control? Inventory control? Control of rate of production? Of material utilization? Effectiveness of labor? Burden expense? Labor turnover? Process standards development? Factory hygiene? Equipment maintenance? Accident prevention? Employee welfare? And last and perhaps most important of all—insurance of constant and continued progress with regard to all of the items listed?

Control of Quality. Limiting ourselves for the moment to the usually accepted purpose of inspection, namely, quality control, it seems desirable that we should answer for ourselves such questions as, Why do we desire quality? and, consequently, Why do we require inspection of product?

The growing experience which any business analyst accumulates continues to impress upon him the fact that a mercenary reason is to be found for almost everything desirable in business, if indeed that thing possesses merit. In other words, a proper profit is a truly moral requisite of any business enterprise. Assuming therefore again that inspection is for the purpose of controlling, or rather producing quality, it develops that quality is desired in order that the enterprise concerned may be profitable. Quality contributes to profit in two distinct ways. In the first place quality increases the sales appeal of a product. Secondly, quality further contributes by maintaining consumer acceptance and satisfaction.

Various writers on the subject of inspection have pointed out that while quality is worth paying for, quality is not necessarily expensive as far as production costs are concerned. If standardization and uniformity of product be constituents of quality, it is certainly true that to this extent improved quality usually leads to reduced rather than increased costs. Disciples of scientific management have learned through repeated proof that standardization and uniformity of product do make for manufacturing economy.

Inspection of product is essential to the attainment of standardization and uniformity, and therefore is an aid in reducing manufacturing costs, as well as eliminating scrap losses, aiding distribution, and thus contributing to profit. Inspection is essential in improving and insuring quality. Our reason for inspection is therefore, profits. Inspection can however aid in producing profits in many ways other than control of quality. The purpose of inspection, broadly stated, is then to produce a proper product at a proper profit.

Organization of Inspection. In undertaking the proper organization of the inspection work of a particular enterprise, it is first essential that the particular conditions under which the enterprise operates receive thought.

To attempt to develop a standardized procedure under which the function of inspection might be applied to business enterprises in general would prove disastrous probably in the majority of applications. In delineating procedure for organization of the inspection function, we are simply outlining a method, and while methods should always incorporate basic principles, the methods themselves can seldom be standardized and prescribed on a uniform basis. One respect in which practically all business executives consistently agree

is that their own businesses are different. It is the writer's belief that in this contention they are correct. When this thought is, however, interpreted to mean that basic principles do not apply to their business, the interpreter is in error. It is not known that any set of fundamental laws or basic principles governing inspection procedure have ever been published, and that no such set of laws exist may very well be true from the fact that inspection as an important function of management is only beginning to be recognized.

It is true that in certain isolated industries the function of inspection has been developed to a fairly high degree. Manufacturing industries as a whole have, however, been pitifully weak in this regard, and were it not for the relatively high development of mass- and line-production methods in America it is improbable that the necessity for, or recognition of, the inspection function as one of the most important functions of management would have arisen. The necessity for *interchangability of parts* required for mass production methods has contributed to a large degree to the development of inspection methods. Interchangeability has required improvement in accuracy and hence improvement in quality.

Another factor has recently arisen in industry which has already and will further result in improvement in quality. This factor is that of *increased competition* due to a change in the direction trend of commodity prices in general. For the last two or three decades at least this trend has been upward. Statisticians agree that the present trend is downward and that this downward trend, at least in its major aspects, will continue for decades to come. Downward trends in commodity prices increase competition, and competition is one of the greatest contributors to improvement in quality. Necessity for improvement in quality is the father to development of the inspection function.

Line or progressive production methods are being rapidly adopted throughout industry and in work of this type *lack of uniformity* becomes an increasingly costly item. Lack of uniformity causes interruptions which may affect a large number of workers. The development of automatic and semiautomatic machinery also requires a higher degree of uniformity than hand methods have required. These developments have resulted in a large number of automatic or mechanical methods of inspection, and it is probable that one of the greatest developments in manufacturing methods as a whole in the next few years will be from the application of such mechanical and automatic scientific methods of inspection. The field for the photoelectric cell alone seems almost boundless. Already it has had application in connection with color shading, counting, measuring dimensional characteristics, the extent of gloss or sheen in finishes, and other quality characteristics. Another application of science to inspection exists in the increasing use of microprojection and magnification equipment.

Inspection as an art is so rapidly gaining in importance that it is indeed dangerous to attempt classification in its present status. Formerly it might have been safe to group industries and say that in general centralized inspection methods would largely apply to certain of these groups and that decentralized inspection would be most logical for other groups, but such is not

now the case. There seems to be almost a stampede from centralized to decentralized inspection methods in nearly all groups of industries.

Measured Quality. In the case of centralized inspection departments, inspection consisted very largely of two divisions, namely, judged quality and measured quality, and as we seem to be going through an evolution from centralized to decentralized inspection, so we seem to be going through correspondingly great changes from judged quality to measured quality. Color shades in time past have almost entirely been a matter of the opinion of experts. We now find ways and means of determining scientifically and in a mechanical manner degrees of variations in the shade of colors. Extent of lustre or sheen, formerly only a matter of judgment, can now be measured and recorded on the dials of instruments. Even the accuracy of measurements which in the past have not been considered subject to argument now becomes a question of degree of accuracy. Where measurements affect appearance for instance, it is improbable that a normal eye can detect a variation of, say, five-thousandths of an inch, particularly if the measurement under consideration is relative to some considerably larger measurement.

On the other hand where measurements affect construction or operation of machinery a variation of five-ten-thousandths of an inch may be sufficient to be detected in the completed product. In the one case we have a variation ten times as great as that in the other case and yet the greater variation is of no consequence so far as sales appeal or consumer acceptance is concerned, while in the latter case the much more minute variation constitutes a defect. The development of scientific and mechanistic equipment for detail accomplishments that were formerly functions of inspection frequently reduces them to elements of production.

Classes of Inspection. When one attempts to classify inspection in terms of centralized or decentralized inspection one is almost bound to conclude that centralized inspection is becoming rapidly obsolete. However, thinking of inspection in its broader sense, should it not be classified as follows?

Product inspection.

Raw materials (purchased items) inspection.

Equipment inspection.

Manufacturing methods inspection.

Fire and accident hazard and cleanliness inspection.

Inventory control status inspection.

Production control status inspection.

Waste elimination inspection.

Burden control inspection.

Employee welfare and labor turnover inspection.

Contribution to progress inspection.

As far as *product inspection* is concerned this subject has already been discussed. The inspection of *raw materials* is becoming increasingly more important. With the development of the chemical and metallurgical professions upon which so many of our industries are becoming increasingly dependent, inspection of raw material in a thoroughly scientific manner is already accepted as essential.

In many of our older industries, the extreme disregard for the condition in which raw material is received is almost appalling. It is true that quantities are usually carefully checked and in some cases quality specification also receives some attention. In many cases, however, management has not even attempted to define, or establish a set of specifications as to what it really desires in its raw material. A careful study of the physical and chemical characteristics of all raw materials, and the effect of these various characteristics on utilization and production will almost always result in manufacturing economies to an extent which cannot be visualized ahead of time.

Equipment inspection should include inspection of first items of product run after equipment is set up for a particular operation or product, assurance that the equipment is producing proper product, that the equipment is operating in as economical a manner as possible, that the speeds and feeds are not only up to the standard specified but that these speed and feed standards have been properly established and that no revision is desirable. Inspection of equipment should also include assurance that there will be maximum safety and minimum effort for the operators.

Manufacturing methods should also be periodically inspected. Determination should be made that operations are being performed according to properly established process standards. Consideration should be given to the question as to whether there is opportunity for revision and improvement of process standards. Labor effectuality should be estimated and again, here, opportunities for improvement evaluated. Inspection for fire and accident hazards and cleanliness should be periodic and frequent, not only for the purpose of preventing loss of plant or time of employees but also for the purpose of correcting the environment of the employee. This is of tremendous importance to efficiency.

Assuming that methods have already been established for properly *controlling inventory* in such a manner that interest on investment and inventories will be maintained at a minimum, the adequacy and effectiveness of such methods should be periodically checked and consideration given to possibilities for improvement.

Similarly, *production control methods* should be periodically inspected, reviewed and revised if desirable. Inspection of opportunities for *elimination of waste* at periodical intervals will be essential. Probably no business enterprise exists in which there have not occurred at times vigorous campaigns for the elimination of waste. However, too frequently such campaigns take the form of relatively infrequent drives. Periodic inspections at predetermined intervals for the purpose of assuring management that waste elimination is constantly receiving attention are important elements of the inspection function.

Application of burden must vary as conditions change. However, there is probably no more insidious malady affecting industry as a whole than the habitual continuation of unnecessary burden expense after the necessity for the particular item of burden in question has disappeared. Burden should receive its periodic inspection.

Employee welfare and labor turnover control methods should also be periodically inspected.

Last and perhaps most important of all, management should have periodic assurance that the enterprise which it administers is constantly showing *progress*. Probably the old saying that "It is impossible to stand still, one must go forward or backward" never had so true an application as it does in a manufacturing enterprise. A periodic inspection for the purpose of appraising the extent to which progress by the organization as a whole has been shown in the current period can be of inestimable worth.

Place of Inspection in the Organization Chart. The function of inspection has reached a fairly high stage of development, at least as far as published information is concerned, in only three industries, namely, ordinance manufacture, the machine tool industry, and the automotive industry. It is readily appreciated that all three of these industries are of the so-called engineering type. In other words, production is largely in accordance with blue prints or designs prepared by an engineering department. In these industries as well as in others, it is argued that one individual, for example, a production superintendent, should not be responsible for both quantity and quality, inasmuch as these two appear to oppose each other. The rapid growth of the importance of inspection in all industries; the more general application of inspection during the course of production for the purpose of reducing scrap material and consequently manufacturing cost; the development of mechanistic inspection methods; and the gradual realization that quality does not necessarily increase manufacturing cost, but in many cases reduces it, are all developments which tend to make it increasingly difficult to segregate inspection from production activities.

While it may be possible to establish as a general rule that final inspection should not be the function of production management, it is in a great many cases impractical to separate inspection during the course of manufacture from responsibility for production.

It is highly probable that responsibility for inspection methods employed should in practically every case rest with the executive whose function it is to direct efforts along lines of product design and development. Obviously the individual who is most capable of approving the design or construction of a product is most capable of judging when such a design or construction has been attained. Here again we have an instance where circumstances alter cases. The majority of industrial enterprises are not the mammoth organizations of which one so naturally thinks whenever the term industry is used. And in the case of the majority of business enterprises, it is believed that a somewhat different basis of separation of authority should prevail. The user of tools and implements is not ordinarily the most capable builder of such tools and implements. Methods after all are tools, inspection methods included. A production executive should be a capable user of methods and equipment. It is questionable whether ordinarily such an effective user of methods and equipment should be expected to be the designer or constructor of the methods and equipment which he may use. It would seem therefore that there should be one executive responsible for production, another executive responsible for product design, product equipment and method development, the latter executive being responsible for all of the various phases of inspection in addition to inspection for the control of quality as discussed in this article.

To expand this idea, it may be said in general that the production executive, or superintendent, should be responsible for the carrying out of methods prescribed by the head of a department of design and development, be he chief engineer, research engineer, chemist, designer, or what ever.

Standards of Quality. Confining ourselves again to the common scope of inspection, namely, that for control of quality, it is essential that standards which establish quality be understood. After all, quality is measured largely by, first, appearance, and second, serviceability. In the majority of manufactured products style is an important element, either in the product itself or in the container in which the product may be sold. Appearance may be made up of such items as uniformity of color, uniformity of shape, and any respect in which the product is measurable by any of the five senses. However, the extent to which the ultimate consumer is able to judge the various factors having to do with appearance is of importance. Long experience with a particular product such as that gained by workers, inspectors and executives, in a given enterprise, often develops an appreciation of variation in appearance entirely beyond that of the ultimate consumer. For instance, it is recalled that in connection with the inspection of a gold-plated clock wheel, which, when it reached the ultimate consumer, revolved at the rate of a few revolutions per hour entirely out of sight inside the case, it was carefully inspected with regard to the concentricity or eccentricity of a very small hub which made a part of the wheel. A considerable percentage of the wheels were rejected because of eccentricity of the surface of this hub, which eccentricity was only visible if the wheel were spun at considerable speed. Such wheels as were rejected for these slightly eccentric hub surfaces were replaced in a lathe and the hub turned down until it was exactly concentric, in the course of which operation the gold plating on this particular surface was of course removed. Due to the fact that the hub and wheel were mounted on a stainless steel shaft, it was impractical to replating the hub. After the foregoing repairing operation the wheels were then inspected and passed, although from the ultimate consumer's viewpoint the quality was less than it had been in the first place from the fact that the machined surface would eventually tarnish because the gold plating had been removed. At any of the operating speeds at which the wheel would ever turn the eccentricity of the hub was not discernible.

The limits of variation, or tolerances, as they may be called in many industries, for acceptable products should be determined from the point of view of variations beyond which the ultimate consumer can discern variation, or beyond which variation in serviceability can become measureable.

Another case is recalled where wooden boxes were rejected for variations from standard amounting to one thirty-second of an inch, where later investigation conclusively developed the fact that normal climatic changes would cause variations of three thirty-seconds of an inch. Still another case is recalled where minute defects in cloth resulted in sections containing the defects being cut out, thus making a larger number of lengths of cloth, a disadvantage in a subsequent process, during the course of which the cloth was covered with rubber so that the defects would have been made entirely invisible. Thus the long experience of the manufacturing personnel had

enabled them to recognize as defects things that in reality were not defects so far as the ultimate appearance and serviceability of the product were concerned. Only by testing the market should standards of quality which are to be established as limits for manufacturing be set up.

In this manner the manufacturer can be assured that he and his organization really appreciate what constitutes quality in their own products. When dimensional appearance or utility standards are established for the government of inspectors it should be ascertained that these limits have sound reasoning behind them.

Types of Inspection. As a means of controlling quality, accepted methods of inspection may be classified in the following groups:

- 100 per cent inspection.
- Random inspection.
- Final inspection.
- Work-in-process inspection.

The determination of the particular type of inspection to be used in a particular industry depends of course on that particular enterprise. In practically every case where 100 per cent inspection of a product, either in its semicompleted or final form is desirable, it should be possible to develop automatic mechanical inspection methods, which will not only locate items of product which do not come up to specification, but will reject them, and in some cases automatically adjust the equipment to eliminate further defects from the same cause.

For instance, we are told of a recent application of the photoelectric cell to a process in which printed wrapping material was being automatically placed around boxes. Variation in tensions or atmospheric conditions, or like causes, might result in improper registration of the printing on the completed package. A photoelectric cell was rigged automatically to check the registration of the printing on the package and make the necessary adjustment when the registrations were not correct.

The extent to which random inspection should approach 100 per cent inspection can only be determined by test. In some instances inspection of one-half of 1 per cent or less, of items manufactured may prove as effectual as necessity dictates. And in other cases much larger percentages must be inspected. It can only be said in this connection that the percentage of work to be inspected should be determined by analytical test and observation of results. There are relatively few products which do not require 100 per cent final inspection. The extent or thoroughness of this final inspection may vary to a considerable degree. However, a majority of industries pay employees in relation to percentage of good work produced, and even if this were not the case, it is certainly true that workers in general take pride in doing good work.

Knowledge that management knows of the quality of the work produced adds interest to the task of the worker, and even were quality not essential as an aid to sales and distribution, it is probable that in the majority of cases the moral effect of inspection and resulting quality would be worthwhile.

As pointed out previously, work-in-process inspection is rapidly becoming more general in industry and is essential in those cases where workers are paid on the basis of good work produced and in those cases where mass, line, or progress production, or production on automatic or semiautomatic equipment is handled.

Control of Dimensional Quality. The limited extent to which gages have been used in manufacturing operations as a whole and the crudeness of those gages which are in use, especially outside the so-called engineering industries, is illustrative of the general lack of appreciation in regard to the extent to which accuracy and uniformity can aid production and reduce manufacturing costs.

Multiplying and dial gages are used relatively infrequently, and the large number of individuals engaged in manufacturing precision items of product who are unable to use a micrometer makes one wonder how mass production has ever made the progress that it has.

The use of microprojection equipment and stroboscopic equipment is relatively new. When determination of accuracy is a real problem these fields should be thoroughly investigated.

Having determined to what extent accuracy is desired and the limits and tolerances of such accuracy through investigation of the consumer's requirements in this regard, and then having provided means whereby readily to gage the product within the prescribed limits, the control of dimensional quality rests much more largely with the inspector of set-ups or first pieces produced, than it does with the operating crew.

Enforcement of Quality Standards. Frequently we encounter among manufacturing executives the complaint that it is difficult to maintain quality standards among workers. An alibi often offered in this regard is that workers are paid an incentive for high production and therefore cannot be expected to produce high-grade work. Such reasoning is fallacious.

As a matter of fact the real difficulty in enforcing standards of quality is the lack of understanding and appreciation of what constitutes quality. So long as inspection is to remain a matter of opinion of a too often dyspeptic inspector, such a lack of appreciation and understanding is bound to continue. The inspection task which cannot be standardized, defined and described in understandable English will usually be found to involve theoretical, impractical and unreasonable measures of quality which have no actual utility, and do not add to product salability or to consumer acceptance.

Workers do like to do good work, and, provided what constitutes good work is intelligently explained to them, the enforcement of quality standards disappears as a difficult task. While it is natural for workers to enjoy producing quality products, it is also essential that an incentive be offered them whereby their income will be improved as quality improves. Thus continued progress along this line will be assured.

Reduction of Scrap. Perhaps one of the greatest opportunities for improving the profit-producing capacity of an enterprise, as a result of inspection, arises from the possibility on the part of inspectors of observing instances where scrap and waste material may be reduced or eliminated. In giving consideration to the accuracy of a product for its particular purpose, the

inspector should also give consideration to the material from which it is produced and to opportunities for reducing the waste which occur in the conversion of the raw material to the finished product. He should divide waste into avoidable and unavoidable waste, and see to it that management is advised of all possibilities for reducing the cost and the amount of material required to produce a given item.

The roving, or work in process, inspector has a fertile field for adding to profits through recognizing his responsibility for being at the necessary points in the manufacturing establishment at the proper time to prevent production of defective work which will later result in scrap. After all, an inspector is in such a position that his perspective should be much better than that of the individual engaged in production.

Team work between inspectors and producers constitutes the only way in which a manufacturing enterprise can be truly and continuously successful. The inspector with a chip on his shoulder and a scowl on his brow is, or at least should be, a thing of the past.

CHAPTER XI

OPERATING DATA FOR LINE OFFICIALS

By F. L. SWEETSER, *General Manager, Dutchess Manufacturing Company,
Partner, Stevenson, Jordan & Harrison*

Manufacturing Costs. Business men generally and industrialists in particular are in accord with the necessity for accurate and prompt knowledge concerning the costs of their operations. However, there is a considerable divergence of opinion as to the methods to be used in the preparation of data and in the presentation and interpretation of the information compiled.

The primary requisites of a satisfactory cost method are:

1. Truthful and accurate reflection of the cost of the various activities.
2. Simplicity and clarity.
3. Promptness.
4. Economy of operation.
5. Suitable comparisons.

A criticism of accounting procedure using job costs is that such information has been largely historical only. The general use of costs of this character has been valuable by providing an experience out of which in recent years there has grown a great improvement. It is generally accepted by the best authorities that some form of standards is essential. These take the form of predetermined measuring sticks of various kinds, such as standards for the cost of materials, direct labor, overheads, etc., as well as budgets of finance, construction, sales, and production.

The greatest value to be secured in the use of these modern standards arises from the psychological effect produced upon the personnel of the organization, particularly the line officials. It makes them cost conscious. The very fact that when properly organized the department heads and executives must give thought to the preparation in advance of suitable standards is sufficient to make them all think about their problems. This is highly desirable. Foremen and executives when first faced with the necessity of establishing standards frequently find it difficult. Like many other things practice makes perfect and it will be found that the solution of the problems lies in the actual doing of the job.

Formerly it has been the opinion of many that standard costs could be applied successfully only to those industries making a standard product with highly repetitive operations. Latterly skill and experience have proved that any and all manufacturing operations may use standards successfully.

Standard Costs. This, then, sets forth some of the principles and procedures necessary for the establishment of a standard cost system. The executive when giving thought to the selection of a method to be used in his enterprise must consider the advantages to be gained in the adoption of a standard cost plan over any other method. It is not a mere compilation of figures prepared in the accounting department after the fact and full of mystery to others. It is a method which provides every department head in advance with accurate allowances showing him the limits to which he can go safely in authorizing expenditures. It shows what the product ought to

FIG. 1.—Executive organization and functions.

cost in detail and separates the cost of inefficiency of operation, thereby pointing out weaknesses to be attacked and the direction required for intelligent cost reduction. Probably the most important report for executive attention is a statement of variations from standard cost.

Organization of Personnel. One of the first steps is to establish the lines of authority and responsibility for the various departments which are to be recognized by the grouping of the personnel. An organization chart is extremely helpful. The idea is definitely to recognize each department activity usually in line with the functions which it performs. Such a chart would show the executive in charge, usually a president or general manager, with his primary subordinate officials not too many in number. Such might be vice president in charge of production, vice president in charge of sales,

vice president in charge of research or engineering, comptroller, and personnel manager. Under each of these heads the operating departments would be indicated such as divisional sales managers, advertising, manufacturing, operating departments and contributory or service activities such as office, receiving and stores, shipping, etc.

It is essential to departmentize activities, using the most natural arrangement, either by locations, functions, or authorities. Always a department must be composed, not alone of groups of equipment or space, but also of persons, in charge of a definite, responsible head.

An example is given herewith:

FIG. 2.—Departments.

It is a good idea to show on such a chart primarily the line of authority extending to all department heads. A supplementary record of responsibilities and duties in narrative form is desirable. The personnel within each department is better indicated on separate typed sheets instead of attempting to include those in minor positions on the chart. A further useful tool is a separate record of the routine procedures for major activities.

The importance of a study of organization and the definite establishment of departments and authorities cannot be minimized. If successful standard costs are expected these are essential. By this means a control of all the activities is made possible because the responsibility both for the establishment of the original standards and the comparisons of actual costs is placed upon the head of the department or activity.

[illegible]

FIG. 3.—Perpetual inventories.

Setting Standards. It should be recognized at the outset that the job of setting standards is really a process of engineering rather than of accounting. The standards must be complete covering all departments and all cost elements of the products made or handled. The procedure requires a review of all available cost and statistical data over a period of three years, if possible, together with a survey of ways and means to determine the lowest possible cost for each element consistent with the quality and service requirements of the business.

When all of the standards are approved they should be introduced into the statistical records in a manner facilitating comparison by totals and items with the actual costs. However, it should not be inferred that the actual cost of jobs processed is necessary. On the contrary, the comparisons are made of elements, activities and departments.

Raw Material Standards. It is impossible to control the costs of materials and supplies without a segregation of these materials in a specially prepared physical space for which a storekeeper is definitely responsible. The receipt, storage and issuance must be governed by properly designed simple forms capable of recording all movements. There must also be a perpetual inventory carefully itemized upon which proper records are preserved.

For each of the items two standards are necessary. First, a standard price per unit and second, a standard usage factor for each of the products to be manufactured. These standards are to be a part of the perpetual inventory record so that when materials are purchased or used a compilation can be made for each accounting period not only of the actual cost of materials and supplies used, but of the variation from standard as well. In some industries it is possible to use standards of price and quantity of materials over a long period of years. In others it is necessary to review and revise the standards annually or semi-annually. Whenever such revisions are made, it is necessary to make a corresponding adjustment of inventory values for the financial records.

The standards of price of materials should be set as near as is possible to the probable actual costs for the approaching period. The standards for quantity or use should be determined by careful analysis of product requirements. This frequently requires an engineering study often resulting in a change in design. The objective is to determine the lowest possible consumption per unit of product to be used as a measuring stick of the efficiency of operations affecting materials. It is not necessary to provide standards either of price or quantity for supplies of indirect items since it is better to determine variations in these costs as expenses. It is necessary to provide such standards for all direct materials to be figured as such in the cost calculations.

Direct Labor Standards. The accepted and approved method of determining the cost of direct labor is by complete analysis of operations and adequate elemental time and motion study. It is essential to organize a time study or standards department with a competent engineer in charge, preferably responsible to the comptroller. In a simple proposition this might even be a part time job or combined with the cost analysis work but for complicated processes or large operations, a real department is necessary. In any event, the careful setting of labor standards will save many times its cost.

First, it is necessary to determine the character of basic data which will be required from which time calculations can be made for any of the products of the enterprise. In a machine shop this would take the form of tables and curves indicating time allowances for all of the machine tools for various feeds, speeds and cuts. Similar tables would cover bench and hand operations.

In assembly departments, the classification of similar products can usually be employed for establishing working tables.

In the manufacture of apparel, similar tables of basic data would indicate the time required for the various operations in the cutting department, such as spreading, marking, cutting, and bundling. In departments using sewing machines, the data would indicate the number and character of seams and the lineal inches of sewing required for the various classes of the product.

In all cases, regardless of the industry, it has been found possible to establish accurately the allowable time limits in such a manner by elements that it is possible and practicable to analyze the products into their time elements.

FIG. 4.—Time study.

Such time limits, usually referred to as standard allowed hours, are readily converted into dollar and cent values by the use of occupational base money rates per hour. Such rates would vary with the market price of labor and the experience and skill required for performing the operation. These occupational rates would also be standardized. In use, the standard allowed hours either as such or converted into money values are used for the determination of the standard cost of direct labor as well as for measuring the efficiency of the operations as performed daily.

One of the most important functions of a foreman in charge of an operating productive department is to observe at frequent intervals the efficiency of each of the operations in his department. By means of a simple calculation

of the standard time or money allowed compared with the actual time or money expended, the variation in cost of direct labor is disclosed. It is desirable that a daily and weekly report should be used for this purpose. It will be seen, therefore, that with this sort of control there is no further necessity for compiling the cost of direct labor since the standard cost of labor is used in all cost calculations and the amount of the variations shows immediately the departure from standard.

For the accounting department a complete analysis of all labor both by weeks and for the accounting period of a month or otherwise is required indicating the different departments with the standard direct labor, actual direct labor, variations as well as the cost of indirect labor analyzed as may be necessary.

Manufacturing Expense (Burden) Standards. It has always been necessary to use some sort of standard for the purpose of application or absorption of manufacturing burden. It is therefore not required that an extended explanation should be made. There are various bases or plans all of which are proper when applied to a situation which fits that particular plan. All of these plans are necessarily arbitrary in character. There are two important essentials: first, the requirement that a reasonably accurate portion of the overhead shall be applied to and absorbed by each of the various products manufactured and, second, that the standards, budgets and accounting for actual expenses shall be set up by departments following the line authorities and responsibilities as established in the organization chart. This must be done regardless of whether the burden rates are by department or not.

Probably the most accurate basis for burden application is by standard hours of direct labor since the whole matter of burden expense is one of elapsed time or hours. In many instances it is entirely satisfactory to use a percentage of the labor cost. This is especially true in industries involving simple operations or low burden expenses. Some authorities advocate the use of machine hour rather than man hour rates, especially for cost centers involving the use of intricate and expensive equipment.

Whatever the basis employed, the items should be classified into fixed charges and controllable or partly controllable expenses.

An essential feature is an expense budget prepared for each department, both operating and contributory, as well as for the general items not applicable to departments. The procedure is to establish a normal point of production for each department expressed in standard allowed man hours, machine hours or direct labor standard cost according to the basis used and for each of the items of expense and allowance for the cost of that item at the normal point of production.

It is further desirable to provide for each department a curve on a graphic chart either for the department as a whole or for the fixed or controllable items separately or for each item if desirable, indicating the amount of allowed expenses at various points of production, both below and above normal.

The accounting department should arrange its distribution records in such a way that the actual costs for each item and for each department will be available for each accounting period so that a report may be prepared

FIG. 5.

for use by the foremen and line executives indicating the variations from standards as well as the budgets and actual costs. These reports should be for the current period and cumulative throughout the fiscal year. By use of such a simple departmental report, the absorption of burden is indicated both for controllable items and for fixed charges as well as the efficiency of the use of the various expenditures.

Standards for Special Conditions. It is sometimes desirable to provide for the absorption of certain expenses in a specific way. An example is the

FIG. 6.—Curve for allowable expense.

cost of purchasing, transporting, storing, and handling materials. In some industries this item is of large importance and obviously has no relation to either the hours or cost of direct labor. The treatment would be to set up a department for material expenses. Standards would represent the cost per unit of quantity for the various classes of materials. The application in the costs is usually to figure the materials net with all discounts deducted adding the cost per unit for materials expense.

Distribution Expense Standards. In addition to providing standards for manufacturing costs, consideration must be given to the cost of distribution sometimes referred to as administrative and selling expenses.

Too little attention has been paid to this class of expenses in cost accounting. The all too common method is to use a percentage of selling price which added to the manufacturing cost is considered total cost. The better plan is to make a careful analysis of all expenses arising after the product is completed and ready for delivery, for the purpose of determining a more accurate basis for absorption. These expenses are usually handling, delivery, direct selling, branch office and home office general charges.

FIG. 7.—Standard specification and cost.

It is commonly possible to establish a secondary cost per unit of product to cover accurately a portion of these items leaving only such expenses to be absorbed as a percentage, as bear a direct relation to the selling price.

Cost Calculations. Instead of depending upon detailed calculations of the actual costs of the various elements determined after the process of manufacture is completed by means of expense ledgers, cost of materials, direct labor, etc., laboriously posted by jobs, the standard practice is to set

up a predetermined calculation on a suitably designed form for each of the products in much the same manner as is commonly used by many companies for estimating. There is, however, a very important difference because under standard cost procedure every item has been previously standardized on a definitely planned program.

For all accounting and statistical purposes the standard cost as calculated is used.

* Roman figures, gain; Italics, loss.

Variations from Standard Cost. In actual operation standards are never precisely paralleled by actual cost. This difference is called variation. Variations occur in all elements of cost and may be either variation gain or variation loss. The standards are set at the point of normal efficient operation. The aim of the executive line officers should always be to secure a variation gain. If operations are at standard or indicate a variation gain there is positive evidence of satisfactory operation. Variation losses must be diligently pursued in consultation with the department head directly responsible.

The accounting set up is arranged to follow precisely the organization chart. One of the most important reports for the executives is the statement of variations from standard costs prepared for inclusion in the monthly or periodic accounting reports.

In the accounting the disposition of the variations may be used either as a correction of the standard cost of sales or be passed to profit and loss. The former is the best practice since it makes it possible to operate the general ledger, balance sheet, and earnings statement on actual costs, while the statistical records and inventories are carried at standard costs in detail.

The Accounting Procedure

The costs must be tied into the financial records in order that complete statistical reports may be available and satisfactory control be assured.

The whole plan for the accounting is presented under four main headings which comprise all of the important functions:

1. Control.
2. Analysis.
3. Informative reports.
4. Comparison.

Under each of these headings descriptions and exhibits will serve to set forth the methods employed to secure the desired results.

The purpose of these methods is to serve as a tool of management definitely aimed toward the stabilization or increase of profits. To this end the reports are to be presented to department heads at frequent intervals for discussion, conference and decision leading to corrective action for cost reduction and other improvements.

Control. The control of all expenditures, assets and liabilities is accomplished by a definitely planned chart of accounts each of which is represented in the general ledger by a controlling account and further by means of the setting up of departments, budgets, and standards.

General Ledger. The function of each of the various general ledger accounts is to control the subsidiary records and to provide the data from which the balance sheet is prepared for each accounting period.

While these accounts have the common function of control, each has some special purpose. "Cash in banks" controls receipts and disbursements regardless of the number of separate banks used. "Accounts receivable" controls individual debtors account. "Inventories" controls the detailed

record of stores, goods in process and finished goods. "Plant" controls plant and property ledger which also carries details of depreciation. In a

The function of the general ledger is control, while that of the voucher distribution is complete analysis. The arrangement shown with the use of decimal classification greatly simplifies the whole accounting and budget procedure.

Classification numbers are coded on all vouchers with vouchers covering all possible transactions in line with the following outline.

The first and second digits to left of all numbers govern general ledger accounts exclusively; following to the right digits three, four, and five represent further classes; then comes a decimal point indicating that the department number follows after the point, thus: 9311.93—93 to the left indicates general ledger account Expense #93, 11 indicates Executive Salaries, and .93 Design Department, covering (A) General Ledger Control, (B) Complete Analysis of Voucher Distribution, and (C) Departmental Expense Control.

Fig. 10.—Chart of accounts

Only the minimum number of both accounts and entries should be permitted in the general ledger.

Each accounting period, usually consisting of one calendar month, is treated precisely the same. Therefore, statements and reports reflecting complete information both as to operations and financial condition, are prepared with no details omitted. The standard monthly closing journal entry is exceedingly simple, usually consisting of five or six items only.

An interesting feature of simplification is that only one ledger account, "inventories" is required for the control of this asset. The details properly analyzed should appear on one of the informative reports planned for this purpose.

In a like manner, only one general ledger account is employed for all expense items "expense," of which the detail is fully covered by means of completely planned departmental analyses based on a chart of expense distribution and reflected in the various statements prepared for executive use.

The benefits derived through planned control, budgets, and standards covering financing, earnings, cash requirements, departmental responsibilities, materials, direct labor, and expenses are considerable.

Analysis. The plan of the accounting is to pass all authorizations for expenditures as well as other required entries including the summaries of the books of original entry, through the accounts payable or voucher records. The only exceptions are the few closing entries for which definitely planned closing journal entries are used. By this means a complete record of all items affecting the various departmental activities is automatically secured without further reanalysis. If tabulating machines are available they may be economically employed, otherwise the best method is individual cards, one for each distribution classification.

Classification symbols are helpful and may be so planned on a decimal classification as to tie in with the general ledger controls and departmental requirements. This makes it possible to apply suitable code numbers on all vouchers, a practice which facilitates rapid entry.

Four forms of vouchers are commonly used; vendors invoices, a credit voucher for use when no invoice is available, a debit voucher for contra entries to be made in red ink and a journal voucher for transfers.

Authorizations for expenditures originate from department heads in the form of requisitions on the purchasing department for materials and expenses while labor expenditure authorizations arise from the pay-roll analysis. When the audit of these authorizations indicates vouchering has been completed entry is made upon the distribution record. Standard journal vouchers are prepared periodically for all required prorrations such as depreciation, insurance expired, taxes absorbed, interest and for summary of books of original entry such as cash received, cash paid, sales analysis, etc.

This plan should be so complete that subsequent reanalysis is unnecessary. Any account which has to be analyzed afterward was not planned rightly in the first place.

Informative Reports. Complete information on every phase of the enterprise is reflected by means of reports and schedules. Direct labor should be reported daily indicating for each department the efficiency of the depart-

ment in relation to normal or budgeted operation as well as the variation from standard cost by operations. This data should be accumulated in a weekly report and for the accounting period.

The manufacturing expense burden as well as the distribution expenses, administrative and selling, are completely indicated by the comparative departmental report compiled for each accounting period and cumulatively to date for the fiscal year for each department separately and by means of a summary showing departmental totals only.

The subject of inventories should be covered by a report indicating the movement of all inventories and subsidiary to the general ledger controlling account Inventories. This report should be arranged in three sections, namely, stores, goods in process, and finished goods. Each of these sections should be further analyzed to break down the inventories into proper items each of which would control subsidiary records covered in the perpetual inventory in detail. For example, the goods in process would be analyzed into materials, direct labor, and burden, at least. This report would also show the values at the beginning of the period, charges, credits and the balance at the end of the period as well as the rate of annual turnover for the period and for the past twelve months.

The stores section may be carried at actual costs, or at standard as preferred, but the goods in process and finished goods section must be at standard cost for all items. The credit to finished goods, namely, the cost of sales, is corrected from standard to actual by means of the variations on standard manufacturing cost.

A statement of the analysis of sales, gross margins, distribution expenses and net profits is desirable arranged in such a manner for each period as to reflect the above items by branches, classified products, salesmen, etc. The study of such a report often discloses hidden losses or opportunities for increasing profits.

A statement of plant and property analyzed into land, buildings, and equipment showing original values, additions, and depreciation is helpful.

The usual statements of financial condition such as the balance sheet and earnings reflect the figures on the actual cost basis disregarding all standards.

Finally a statement of variations from standard costs summarizing both manufacturing and distribution departmental activities is essential.

Budgets

Budgets and standards are often confused. While they have a distinct relation to each other they are different in character. Standards are measuring sticks set up in detail for the purpose of controlling the various cost elements and determining variations. Budgets, excepting in governmental affairs, are not appropriations for expenditures but are a means provided for the purpose of making the entire organization think about its job in advance. There should be provision for budgets of sales, production, finance, construction, research and expense. Budgets should be compiled by means of conferences composed of the personnel which is best informed about

the particular subject. They must be coordinated with the other activities, subjected to the accounting knowledge of the comptroller's department, reviewed by the high executive and finally adopted by mutual agreement.

Referring to the production budget in particular, it should be established on the basis of normal production reflecting both the normal point of production, usually expressed in standard allowed hours, and the various expenses both controllable and fixed, allowable at the normal point of production. The relation between the standard expenses and the budgeted production establishes the burden rate. Separating this rate into two parts respectively for the controllable and fixed items provides first, for the control of the actual controllable expenses and second, for indicating the idle capacity of the plant due to under absorption of fixed charges.

The normal point of production should be established for manufacturing operations without regard to the volume of sales quota. The function of the sales department is to produce a satisfactory volume to utilize the existing facilities or to indicate by a larger quota the desirability of a construction program. If the sales volume falls below the normal point of production thereby reducing operations to less than normal, the cost of unabsorbed fixed charges should be considered as idle capacity and charged to profit and loss as a responsibility of management.

Incentives. During recent years the value of the incentive plans for the compensation of labor is being definitely recognized. One of the advantages of the use of standards and budgets with the resulting variations is that almost no additional statistical detail is required for the preparation of suitable incentive plans either for direct labor, primary executives, or key men. In fact when incentives are desired, it is usually necessary to establish budgets and standards substantially as outlined before such plans can be installed.

Expense of Operation. Economy is just as essential in office and clerical work as elsewhere. The simplification of cost accounting and statistical reports through the use of budgets and standards leads to the greatest economy of operation possible. Direct methods are employed throughout and many unnecessary details are eliminated. The principle of the use of exceptions prevails. Standards are carefully thought out and applied in such a way that if no variation losses are indicated, satisfactory operation of the enterprise is assured.

CHAPTER XII

PURCHASING

BY EDWARD T. GUSHÉE, *Purchasing Agent*, AND F.A. COMPTON, *Assistant Purchasing Agent, The Detroit Edison Company*¹

Importance of Purchasing. During the last decade there has been a steadily increasing pressure on industrial management to reduce production costs. Competition within an industry itself and the development of substitute products are the incentives for this urge.

The efforts of management in solving these problems have, during the last decade, been devoted largely to problems of production and distribution.

By production is meant the processing of the raw materials after they have been received in the plant. So far as the development and improvement of labor and machinery are concerned, scientific management has without question been quite successful.

But a study of the distribution of use of the average dollar of gross receipts in industry will reveal that this effort has been concerned with roughly 17 per cent of industry's expense, while an item of roughly 57 per cent has been largely neglected.

In industry as a whole, 57 cents of the manufacturer's dollar is spent for materials, 17 cents for wages, and the remaining item of 26 cents goes for overhead, interest, taxes, and profit.

FIG. 1.—Manufacturer's dollar. Average division of industrial receipts computed from data of Census Bureau.

These figures, shown in Fig. 1, are derived from data collected and published by the United States Census Bureau. Obviously, therefore, purchasing is a phase of management which requires thorough study and efficient performance. The importance of proper purchasing is emphasized by the fact that gross sales must be increased \$10, on

¹ Compiled from "Scientific Purchasing," by permission of the authors, Edward T. Gushée and L. F. Boffey, and the publishers, McGraw-Hill Book Company, Inc.

the basis of average profits, to compensate for each dollar of waste in purchasing.

Management has unquestionably lagged in its appreciation of purchasing and has not tried to apply to it the principles of efficiency which have revolutionized production. It has watched and carefully controlled the expenditure of 43 cents of each dollar of production cost which goes to labor, administration, overhead, interest, taxes, and profit and has succeeded, on the whole, in getting full value for that expenditure. It has given only cursory attention to the 57 cents of each production dollar which is spent for materials, and in consequence it has allowed—and in many industries still allows—a large portion of that amount to be wasted.

Some far sighted companies have recognized purchasing as a major function and are developing their purchasing organizations along scientific lines. So little concerted study has been given to purchasing, however, that there are virtually no data, based on the actual experience of other organizations, which can be referred to in building up a purchasing organization. From this standpoint, it may well be asserted that scientific purchasing is in the same nebulous state which characterized scientific production a decade ago.

The full development and advantages of scientific purchasing cannot be attained by individual effort. They can be attained only by universal understanding and application of the principles which govern sound purchasing. This is true, because materials pass through many hands and manufacturing processes before they reach the ultimate consumer. The finished product of one manufacturer is raw material for another. If only a single manufacturer in the chain uses scientific methods of purchasing, the resultant saving is trifling in comparison with the saving which might be made by the application of scientific purchasing to all in the chain.

Principles Applicable to Large and Small Organizations. The discussion and conclusions that follow are equally applicable to the small as well as to the large organization. In a small organization the purchasing department might properly consist of a purchasing agent and two or three assistants while in a large organization the purchasing function might be handled by a director of purchases assisted by a staff numbering a hundred or more persons.

Functions. But regardless of the size of the organization, the purchasing function, properly organized, consists of the following:

1. Administration.
2. Buying and follow-up.
3. Accounting.
4. Inspection and material study.
5. Economics.
6. Salvage disposal.

In some types of organizations traffic and stores, or either, may operate as a division of the purchasing department. Always there is a close relation of these two functions to purchasing.

Administration. Administration of the department is obviously the function of the purchasing agent. He must supervise all the divisions, keeping in close touch with the work of each. He should approve all major requis-

tions before they are passed to the buying division; approve the award of all major contracts and orders; decide all questions of policy in dealing with other departments of the company and with the public; maintain close contact with the executive, operating, and engineering officials of the company; conduct negotiations with sellers on all important purchases; and adjust differences which arise in the performance of contract.

Order Division. The order division, comprising the buying and follow-up groups of the department, should come under the direct jurisdiction of the purchasing agent's chief assistant. In small organizations the assistant himself will take over the major work connected with this division, keeping the purchasing agent fully advised of all important transactions and developments. In larger concerns the assistant purchasing agent will head, either directly or through the medium of another assistant or chief clerk, a staff of specialized buyers, each of whom handles the purchase of one or a related group of commodities.

The grouping of commodities, for the purpose of specialized buying, will vary according to the manufacturing requirements or operations of the company, but for purposes of illustration the following are indicated:

1. Iron and steel products.
2. Non-ferrous metal products.
3. Textiles and chemicals.
4. Lumber and wood products.
5. Mechanical equipment and supplies.
6. Electrical equipment and supplies.
7. Paper, printing, office equipment, and supplies.
8. Maintenance material and supplies.
9. Miscellaneous.

This grouping is wholly suppositious, and the obvious plan to follow is a divisional arrangement that will insure competent and thorough supervision of purchases in all markets from which the company's requirements are drawn.

The size of the company and the magnitude of its operations will control the number of workers in each of the buying groups. There can be no uniformity on this point, as one buyer may need several assistants to fulfil his duties, while another may require only the part-time service of a stenographer.

Putting the order division in charge of the assistant purchasing agent provides the individual control which is necessary for best results. His supervision will insure that all the buyers follow the same fundamental practice and will establish proper authority for stabilizing the departmental load when one buyer is overcrowded with important negotiations. The assistant purchasing agent will be the point of contact between the buyers and the purchasing agent and will assume the responsibility for the routine of the division, bringing before the purchasing agent all special problems connected with ordering and follow-up which require the latter's personal attention.

The follow-up of orders may or may not be assigned to a special subdivision of the department, depending on the volume of orders issued. Where a subdivision is necessary, it should be recognized as part of the order division. The follow-up clerks should report to and receive instructions from the buyers. The buyer is in the best position to know the relative importance of

delivery on each of the orders he issues, the period normally required for manufacture and transportation, the best method of expediting in cases of emergency, and the steps to be taken if the source of supply falls down in a particular transaction. Even more important is the psychological effect of the buyer's supervision of the follow-up of his orders. He knows and is known by the sales representatives of the concerns from which the goods are ordered, and he can get individual and special attention in urgent cases, where a routine follow-up might be ignored or casually treated. It is a fundamental of purchase organization that the follow-up work shall come under the jurisdiction of the buyers.

Economics Division. The economics division is an extremely important part of the purchasing organization. Broadly, the function of this department is to maintain all records relating to the prices of products, to study materials and markets, to analyze the prices paid for commodities and equipment, and generally to point the way to savings through more intelligent specifications and supervision of sources of supply. This division or its equivalent is essential for every purchasing department which expects to make major savings. Economy in purchasing is not a matter of selecting the lowest of a number of bids, but of knowing that the material bought is adapted for requirements, efficiently produced, and bought at a price which represents a fair profit to the seller.

It is desirable that the head of the economics division of the purchasing department shall be a commercial economist. He must have a thorough grasp of the conditions which affect supply and prices, and the ability to present those conditions in text and graphic form for quick visualization by the purchasing agent and the buyers. Even the comparatively small concern, provided it has a volume of buying sufficient to justify rudimentary centralization, should provide the purchasing agent with an assistant who is competent to handle the economic work of the department. Without such provision, the purchasing of the company will follow rule of thumb rather than scientific lines.

Accounting Division. The accounting division of the department will have as its primary duty the checking of all invoices, verifying the prices charged, insuring that all discounts, allowances, and earned concessions are shown on the bills, and arranging for adjustments for overshipments, erroneous charges, and defective or improper material. The work of this division should come under the supervision of a chief clerk.

Inspection Division. As its name indicates, the primary function of the inspection division is to determine that all materials and equipment delivered are in strict conformity with the specifications. The name inspection, however, does not imply the full functions of the division. It should also be charged with responsibility for the initiation, maintenance, and revision of specifications and standards; and likewise, with responsibility for the investigation of new materials and new sources. All of the efforts of the purchasing organization in building up adequate specifications and purchasing to them will be minimized if no attempt is made to determine that actual deliveries conform to the specifications and this determination is, of course, the primary function of the inspection division.

Salvage Division. The last of the major divisions of the purchasing department has for its function the salvage and disposal of scrap material. The sale of scrap or obsolete equipment is almost invariably assigned to the purchasing department, but in most instances the function is indifferently handled. The tendency is to regard any recovery, no matter how small, as so much "velvet" and the accepted method is to invite a scrap dealer to make an offer for the available material and to accept whatever he deigns to bid. Where this procedure is followed, much material which could be adapted or converted to the company's own use is literally thrown away and other material is sold for an inconsequential sum because the advantages of reasonable sorting and classifying are ignored. The salvage division of the purchasing department can save large sums for the company by using reasonable care and proper methods in its work.

FIG. 2.

Stores and Traffic. Two other functions may or may not be regarded as divisional parts of the purchasing organization. These are stores and traffic. The question as to whether the purchasing agent should supervise these functions is a moot one; there are apparently convincing arguments to be expressed on both sides of the question. The arguments are convincing, however, only in relation to the particular organization for which they are advanced. The question is really one to be settled as an individual company policy. For the purpose of this discussion, the point as to whether the purchasing agent should directly supervise stores and traffic is not important.

The important thing is that the relation of purchasing to stores and traffic must be intimate. The intimate relation can be maintained, however, by heading stores and traffic with responsible officials whose authority over their own department parallels that of the purchasing agent over the purchasing department, just as readily as it can be maintained by having stores and traffic operate as divisions of the purchasing department.

A typical plan of organization is illustrated. This form of organization is applicable to a concern with a large volume of purchasing. It can be added to or modified, however, to cover the needs of a particular concern, because it follows essentially the outline given in this chapter.

Basic Principles. The following principles govern the organization and activities of a purchasing department if it is properly to function as a component part of an industrial organization.

1. Centralization.
2. Personnel.
3. Records.
4. Coordination.
5. Know what you buy.
6. Standards and specifications.
7. Fair dealing.

First Principle, Centralization. It is impossible for real economy to be attained in the purchase and utilization of materials if the administrative officers, the production staff, the sales department, and the engineers all dabble at the process of buying. The function of purchasing must be assigned to a thoroughly competent individual whose responsibility and authority must be recognized both within and without his organization, and to whom must be given the cooperation of other departments and the encouragement, guidance, and especially the undivided backing of the executives of the company. He should be held responsible for results, and not hampered in the accomplishment of his duties.

True centralization of purchasing requires that the purchasing agent's authority and control of purchases shall be as absolute and definite as the treasurer's control of finances, the sales manager's control of sales, the plant manager's control of production, and the engineer's control of design.

Against this contention two arguments are frequently voiced. First, that the purchasing agent, as a type, is not equipped for such authority and control. The argument is weak. The type of purchasing agent who cannot adequately assume responsibility and properly exercise authority over purchasing has no place in the modern business organization.

The second argument is that a purchasing agent cannot be expected to possess such a fund of knowledge that he is sufficiently familiar with all materials and equipment in order to exercise the right of selection. As a matter of fact, the purchasing agent can, and should, have an intensive knowledge of what he buys, but it is admitted that arbitrary selection is not his prerogative. The argument, therefore, does not affect the principle of centralization.

In a broad sense, the determination of what to buy is not a purchasing function. For a purchasing agent to decide that brass instead of steel shall

be used for the composition of a particular part of the company's product, or that a milling machine instead of a shaper shall be purchased to round out the plant's mechanical equipment, or that oil shall be burned instead of coal, would obviously invest the purchasing department with duties and responsibilities that properly belong to production and engineering. The need and specification for goods arise outside the purchasing department and must be expressed before the purchasing department begins to function.

The direct interest of the purchasing department in the determination of what to buy has to do with the specifications for the goods. In the preparation of specifications the purchasing department should be consulted so that, as finally drawn, the specifications will allow for reasonable competition to be utilized and will stipulate standard sizes, items, and performance in preference to special requirements. Given such specifications, a purchasing agent should be competent to select from available sources of supply the one, or more, best fitted to provide the goods. If he does not possess that competence, he is not the right man for the job.

The argument that the department or individual which determines that a forging instead of a casting is to be used for a given purpose on the company's product should also determine the source from which the forging is to be purchased is fallacious. It is just as reasonable to argue that the designing division must control the production processes for the products it designs, the production division must handle the sale of the goods produced under its supervision, the sales division must control the money resulting from the sales it makes, or the financial division must determine what shall be paid for purchased goods because it controls the funds of the company.

The right of the requisitioning department to specify what is required should not be disputed by the purchasing staff, for the user or designer assumes the responsibility for performance if the specification is followed. This should not be interpreted as barring the purchasing department from all participation in the determination of what to buy. There are two inherent privileges which should be accorded the purchasing department in regard to specification: first, to ask questions; second, to make suggestions.

If a specification is unduly restrictive, narrowing the choice of sources of supply to a point which stifles competition or forces the bidders to quote high prices as a measure of protection against the severe stipulations, the privilege of questioning should always be exercised by the purchasing department. In the majority of cases this will lead to modifications, for users and designers have a definite interest in keeping down production and operating costs.

If the purchasing department, by virtue of its knowledge of materials, standard specifications, sources of production, manufacturing facilities, and economic conditions, considers that a specification should be revised along definite lines, it should suggest those revisions. The suggestions should be explicit, pointing out the advantages which will be gained if the revisions are made.

In substance, centralization of purchasing insures that all purchases shall be handled and consummated by the purchasing division; that the purchasing division shall be responsible for the procurement of materials or

equipment in conformity with specifications or in keeping with the requirements for which the goods are specified; that the selection of sources of supply shall be the function of the purchasing division; that while intermediate negotiations may be conducted between sales concerns and other departments of the buyer's company, such negotiations shall be with the knowledge and approval of the purchasing agent; that the consummation of all purchase transactions shall be left to the purchasing department, and—by no means least important—that these prerogatives of the purchasing department shall be understood and willingly adhered to by all other department heads and officials, without surrendering their own rightful functions.

Advantages of Centralization. Under these circumstances, centralized purchasing may and should achieve the following fundamental economies:

1. Center authority and responsibility for purchases, instead of dividing the responsibility among a variety of officials, many of whom lack the commercial instinct and economic knowledge necessary for proficient buying.
2. Permit commodity standards to be set for all using departments, thus curtailing the number of items that must be carried in stores and releasing much capital that would be tied up if each using department bought and carried its own reserve supplies.
3. Combine the requirements of all using departments, thus permitting purchases to be made in large volume with consequent savings of large amounts by reason of lower unit prices.
4. Eliminate waste and extravagance through the maintenance of records to show the normal rate and frequency of consumption for commodities, thus providing a check against excess consumption.
5. Enable purchases to be made when conditions are most favorable, by means of market study and analysis which will indicate when the time is propitious for buying.
6. Establish sound specifications, by means of records, research, engineering counsel, and cooperation of using departments, to insure that the quality of materials purchased shall be precisely adapted to requirements.
7. Analyze the prices paid for materials, thereby inspiring the utmost economy in production by manufacturing vendors, eliminating excess profits, assuring a fair margin to suppliers, and securing value for the company's expenditures for materials.
8. Encourage the development of manufacturing methods and substitute commodities which will pave the way to economies in the purchase and use of materials.
9. Simplify and expedite inspection and approval of materials, and accounting and payment of bills.

The first step in the application of scientific purchasing, therefore, is to centralize the purchasing function.

Second Principle, Adequate Personnel. Until recently the unwisdom which characterized the attitude of many industrial executives toward the function of purchasing inclined them to consider that no special training or qualifications were required for the purchasing agent. The errors of omission and commission made by an inexperienced and unqualified purchasing agent may and frequently do cause tremendous financial losses. Stand-

ards by which a purchasing agent should be judged are (1) absolute honesty, (2) a sound conception of engineering and manufacturing processes, (3) ability to reason calmly and logically, (4) executive ability, (5) ability to deal with men, and (6) comprehensive knowledge of economics.

Third Principle, Adequate Records. The third principle concerns the preparation and maintenance of adequate records. A purchasing department may be said to attain perfection when it buys the right quality of material, in the right volume, at the right time, from the right source, at the right price. As a corollary, data should be compiled which will in general indicate (1) what to buy, (2) when to buy, (3) how much to buy, (4) where to buy, and (5) how much to pay. The possession and use of such data would not enable a purchasing agent to be infallible, because purchasing cannot be reduced to an exact science, but the lapses will be encountered less frequently than when hit-and-miss methods are relied upon.

Sources of Data. The sources of the purchase data which should be compiled in every purchasing department may be roughly divided into three classes:

First, data on the company's purchases, obtainable from the purchasing agent's own files, such as quantities purchased, dates of purchase, prices paid, quotations from unsuccessful bidders, and intimate information about sources of supply. These data originally must be prepared in some form or other for use in the ordinary routine work of the department. It remains for the data to be compiled and arranged in convenient form for ready reference and analysis. The task is important and usually difficult, but the results provide a great compensation for the time and expense involved.

Second, data on markets, including information on production, consumption, shipments, stocks and marked prices, volume of employment, wage rates, and activity in basic industries.

Third, data on materials, including a specification file; test reports; studies of materials; and information on the sources, supply, and uses of materials.

Fourth Principle, Coordination. The fourth principle is coordination. Coordination of the major units of an organization is essential for its commercial success. There are functions of the purchasing department which must not be usurped by other departments. Purchase negotiations with vendors must begin and end in the purchasing department. In the deliberations within the company as to the selection of materials, the purchasing department should have a voice and concur in the final decision, but its entire function should be coordinated with other departments so that the prerogatives of all may be respected.

A decision as to when to buy, based only on the economic studies of the purchasing department, may be incorrect from the viewpoint of the demands on the company's treasury. Only by considering all the facts can a proper decision be made.

It is the function of the production department economically to produce the product to be sold and as a corollary it can demand that the raw materials must be adaptable to economical production methods. One function of a real purchasing department is ever to be on the lookout for new materials

which will either reduce production costs or increase the quality of the product.

This means coordination of the two functions, and it can best be established by heading both departments with competent officials. The purchasing agent in relatively small concerns, and the specialized buyers in large corporations, must possess a thorough knowledge of manufacturing processes and the uses to which materials are put. The wider that knowledge, the more effective will be the service rendered by the purchasing department to the production staff.

Fully as important as the relation between purchasing and production is that of purchasing and engineering. The function of the engineering department is to design, develop, and assume responsibility for the quality and performance of the products to be manufactured.

Coordination of purchasing and engineering is vital to the best interest of the business, yet in many organizations these two departments are constantly at issue, constantly working at cross-purposes. The engineer prepares specifications which are scientifically exact but which may be commercially impossible. He insists that they be followed to the letter and resents the effort of the purchasing department to modify the specifications in diction or in limitations so as to increase competition and reduce prices. In return, the purchasing agent scorns the scientific attitude of the engineer and sarcastically suggests that specifications be prepared with at least a smattering of attention to market conditions, standard sizes, and commercial practice.

It is certain that many current specifications are not commercially practicable. But the engineer is not wholly at fault for the deficiencies in his specifications. He is not expected to possess the commercial knowledge which is one of the purchasing agent's chief characteristics. Inadequate specifications bear testimony to the fact that engineering and purchasing are operated as separate units instead of as correlatives in the business organization.

Only by coordination can the technical skill of the engineer be combined with the commercial wisdom of the purchasing agent to produce specifications that will represent the greatest value in both performance and cost.

Fifth Principle, Know What You Buy. To be familiar with what he buys is one of the most important qualifications of a buyer.

Scientific purchasing reverses the old theory that the buyer is inherently at a disadvantage in dealing with the seller, because of the latter's superior knowledge of what he is selling. It requires the buyer to assume the aggressive instead of the defensive in negotiations, because it is his duty to specify what he requires, to find the right source for its production, to buy at the right price and at the right time. To accomplish this, the buyer must know all that can be reasonably learned about the materials he purchases.

Sixth Principle, Standardization. The sixth principle concerns material standards and specifications.

To illustrate the importance and possible results of standardization the following tabulation is given to show what was accomplished after what, in some cases, was a preliminary study of the situation.

Material	Variety and sizes before standardization	Variety and sizes after standardization
Paving brick.....	60	4
Files and rasps.....	1,351	454
Range boilers.....	130	13
Milk bottle caps.....	10	1
Reinforcing steel.....	66	11

In one particular company before a study was made eighty-eight sizes of conduit outlet boxes were used. In each size both black and galvanized boxes were used. After standardization, only six different sizes were used and they were all galvanized.

Using departments cannot be expected to requisition standard goods unless the standards are established and brought to their attention. From the standpoint of the using department, any material which can be obtained in the market is standard. Thus, the office manager who selects a desk from a catalogue, and the engineer who stipulates fifteen-sixteenth-inch steel bars for a particular manufacturing purpose both feel that they are specifying standard items because the purchasing department can procure both from stock.

But standardization involves much more than the selection of stock items.

In the storeroom of one large corporation a supply of four different brands of lubricating oil is maintained, all intended for the lubrication of the same type of machinery in different departments. Each brand represents the choice of a different requisitioning official. Three of the brands could, and should, be discarded, thus enabling the buyer to quadruple his volume of business to one source with consequent lower prices, and probably to cut the quantity of oil in storage to a quarter of what is carried. The same lack of standardization and the duplication of stores might be observed in hundreds of other items in that plant, and the condition is more or less characteristic of every manufacturing plant.

Specifications. Hand in hand with the principle of standardization is that of clear and definite specifications for goods to be purchased. This does not imply that a technical or engineering specification must be compiled for every item that is purchased, although, as will later be discussed, there is great need for more and better engineering specifications. Essentially, however, every requisition for goods to be purchased is a specification. Whether the item is a broom or a carload of lumber, a pin or a locomotive, the requisition issued to the purchasing department should convey a complete and intelligible description of what is wanted.

Importance of Specifications. Specifications are important from many angles. Some of the advantages of preparation of specifications and the use thereof may be listed as follows:

1. It enables the buyer to know the definite requirements of what he is buying.

2. It makes possible real inspection to determine whether correct quality of material is being furnished.

3. It brings up to all interested parties, buyer, designer and user, the question of whether a given material is not good enough or is too good for a particular use.

4. It widens the field of sources of supply, all vendors being able to bid on the same basis.

5. It reacts to the benefit of the manufacturer of good materials in that he knows he is not bidding against unfair competition, i.e., against some other manufacturer furnishing inferior material.

6. It interests the designing and operating engineers in the commercial variations in quality, the standard qualities available and the excess cost of variations from standard quality.

Preparation of Specifications. In preparing a specification file, different companies will approach the work in the manner best suited to their own requirements, but in every case it is advisable that one individual or group be made responsible for the specification file. In many instances the engineering corps is the logical source for such a file. Before any specification is finally decided upon, it should have the approval of the engineer, of the using department and the purchasing agent. If the company is of such size as to warrant a research department or a materials engineer, they also should approve specifications. Of course, standard specifications should be used when possible—such as government, A.E.S.C., A.S.T.M., etc.

A suggested method of organizing a specification file is outlined below. This is merely an outline as a guide to the fundamentals and will, of course, differ with various companies.

Anyone desiring a specification should proceed as follows:

1. Ascertain from the specification division, purchasing department, if the desired specification is in the approved file. If so, copies can be obtained at once.

2. If a specification has not been prepared the specification division will undertake to assist in the preparation of the desired specification or will write the specification, subject to approval of the department.

3. Before a specification is printed and filed its form and contents must be approved by the department or departments responsible for its application. Such approval shall be made in writing upon the final typewritten copy. Approval must be made by the department head or his duly authorized representative. The chief of the research department and the purchasing agent shall also approve all specifications.

4. The specification division is responsible for the printing of approved specifications and for the maintenance of the specification file.

5. The specification division is responsible for all proof reading and will see that the printed specifications are exact copies of the approved typewritten specifications.

It must be expressly understood that the department requisitioning material under a given specification is entirely responsible for the application of that specification to the job in hand.

6. *Revision.* Specifications are subject to revision whenever required to keep them up to date. The inspection division will see that such revisions

are made and for that purpose will circulate all specifications from time to time in the responsible department. The responsible department shall determine whether a specification requires revision or not.

a. If a specification does not require revision it will be approved by the responsible department in writing and returned to the inspection division for filing.

b. If the specification requires revision the responsible department will make such revision in writing and return the revised specification to the specification division for typing in the revised form. The procedure will then be as outlined above.

7. *Use.* When requesting quotations the purchasing department will send to the firms asked to quote a copy of the specifications covering the material under consideration. When order is placed this specification will be made a part of the formal order.

Inspection of material will be made to approved specifications. It will here be of interest to note what a specification should be. The following five points cover the question.

1. Should be specific.
2. Should accurately describe the material and its properties.
3. Should describe methods of inspection and testing.
4. Should be easily read and understood and worded as simply as is consistent with clear meaning.
5. Should adhere as closely as possible to nationally recognized standard specifications.

Not until standards are established for all equipment, materials, and supplies used in the plant, and not until clear and intelligible specifications are a requisite for every purchased item, can the full benefits and economies of scientific purchasing be realized.

Seventh Principle, Fair Dealing. The last principle concerns fair dealing with the supplier. An essential function of the purchasing department is the building up of dependable sources of supply. This can be accomplished more easily by having all of the relations with vendors characterized by a constant fairness. It should begin with the reception of salesmen. It should be prompt, courteous, and businesslike.

In negotiating with suppliers regarding a prospective order, fair dealing requires that strictly ethical methods be followed by the purchasing agent. To intimate to a salesman that his price is high when it is actually low, to introduce imaginary competition in order to coax an extra discount from the salesman, to misrepresent directly or by implication to bidders for the purpose of exacting concessions which would not otherwise be allowed—these are tactics which belong to the past era of buying. They may succeed now in isolated cases, but salesmen are quick to detect the haggling instinct in buyers, and when dealing with that type will in self-defense name initial prices which include a margin for bartering.

Fair dealing requires also that the buyer shall not take advantage of the seller when he knows that the latter has erroneously presented an estimate

which will mean a loss to him on the transaction. There are occasions when goods may be designedly and legitimately bought at less than the seller's cost of production. This is sometimes agreed upon between manufacturers and suppliers in industries selling direct to the public. The seller assumes the loss to have his goods established as "standard" by the manufacturer and makes his profit on replacement sales to the direct consumer.

In the general run of transactions, however, the buyer should expect the seller to make an adequate profit. That desire need not be altruistic; the experienced buyer is inherently shrewd and knows he must have dependable sources of supply. He knows, too, that a concern which makes no profit will not long continue as a source of supply.

A fair price, which permits the seller to make a reasonable profit on the basis of economical production and have funds available for development, is essential in modern business; not merely from the standpoint of the golden rule, but as a matter of self-interest to buyers as well as sellers.

Fair dealing also entitles the seller to know when and for what reason he has been unsuccessful in bidding on an order. There are sound reasons for not informing a bidder the price or terms which have been named by his competitor, but no possible harm or violation of ethics is risked by telling the unsuccessful concern that the price or quality or delivery of another supplier was more advantageous in the buyer's opinion.

Confidence and cooperation between those who buy and those who sell are an imperative need in industry. Fair dealing is a vital principle of scientific purchasing, for business relations to be sound must be on a basis that will leave both buyer and seller fully satisfied with the completed transaction.

Conclusions. Scientific purchasing points to many conclusions which present day management cannot afford to disregard.

First of these conclusions is the conception that buying must not be regarded as an incidental function which can be trusted to anybody and everybody. The successful purchasing agent of today is the product of a thorough and rigid course of training. His education in buying has been acquired in the school of experience. This education, however, has involved a roundabout course and a considerable expense to industry. For every purchasing agent who has attained reasonable proficiency and reasonable success in the past twenty years, there have been a dozen or more who have failed—costly sacrifices on the altar of industry to the false dogma that "anybody can buy."

For the future, management cannot afford to try out a dozen men to select one who is qualified to buy. It must choose and develop its purchasing agents with the same judgment and discretion that govern the choice of production, administrative, and sales executives. The attention now given to purchasing in the management courses of business schools and the special training which large corporations give to likely individuals in their own purchasing departments are indicative of the fact that the day of casual selection of purchasing agents has gone by.

Second, scientific purchasing will simplify the process of simplification in industry. The movements inaugurated by the Department of Commerce

to eliminate costly and unnecessary varieties, sizes, and styles of commodities will, when successful, establish savings of hundreds of millions of dollars a year to manufacturers and consumers. This saving can be realized only when it is fully comprehended, and the movements supported by industry. The path of progress for simplification runs parallel with the path for scientific purchasing.

Third, scientific purchasing will enhance the use of specifications in buying. The buyer will know what he buys. He will attach little value to proprietary names and trademarks, except as they represent actual quality and known ingredients in the goods they identify.

Fourth, scientific purchasing will establish an equitable relation between cost of production and selling price. The growing appreciation of price analysis in purchasing points to a great future development in this phase of buying.

Fifth, scientific purchasing will improve, and in some respects revolutionize, sales methods and sales organization. The itinerant peddler who sells carbon paper today and soap tomorrow will find little welcome in industry, nor will the "high-pressure" type of salesman. Selling, in the future, will resolve into an intelligent study of the buyer's problems, to determine how the seller's products and facilities can best be utilized by the buyer. The result may be fewer—but better—salesmen, with consequent reduction of sales costs.

Sixth, scientific purchasing will probably lead to some forms of cooperative buying. The extremely small manufacturer will never be able to employ specialists in purchasing, because the cost of this type of organization would be out of proportion to his expenditures. The tendency will be for him to allow his large customers to buy the raw materials and principal products which he uses directly or indirectly to make up their orders. Thus a large buyer, when contracting for coal or fuel oil, will include in his specifications the requirements for several of his small sources of supply. Each of the sources will get all of the advantages of the large buyer's organization, research and purchasing power. The same procedure will apply to metals and textiles and lumber and other major commodities. The application of this plan may be observed today in some quarters; its extension seems logical and certain.

Seventh, because scientific purchasing is founded on the correct interpretation of business trends it will help to stabilize business conditions. It will check the type of overbuying which tends to accelerate rising prices and encourage ill-advised expansion, and thus, it will moderate the severe reactions which come from overexpansion.

Finally, in summation: Management seeks to reduce production costs. It has gone far in that purpose by developing the machinery and methods of production and increasing the productivity of labor. The greatest possibility of further progress is found in scientific purchasing, i.e., in the proper expenditure of the 57 cents of the manufacturing dollar which is spent for materials. The concern which neglects that course will find it impossible to compete with organizations which apply the principles and methods of scientific purchasing.

It is not the individual concern only that will profit by this application. Scientific purchasing aims not for the lowest price but for the greatest ultimate economy in the purchase and utilization of materials. It strives to eliminate the waste which results from haphazard selection and inadequate methods of buying. Its universal application will lead to greater efficiency, greater economy, and hence, greater prosperity throughout all industry.

From this broad economic aspect, as well as from the standpoint of the individual concern which imperatively needs cost reduction to extend the market for its products, scientific purchasing is a phase of management which must be studied, comprehended, and applied. To neglect it means to be outdone, in the competitive race of industry, by those progressive concerns which grasp its advantages and reap its profits.

CHAPTER XIII

STORESKEEPING

BY STANLEY P. FARWELL, *Director, Business Research Corporation*

The functions of the stores department include generally:

1. Checking in and placing newly received items.
2. The systematic housing and safekeeping of parts and materials.
3. Disbursements under the authority of requisitions.

General Requirements. The department constitutes the connecting link between the production, or planning department, and the manufacturing departments. Therefore, the nature of the manufacturing processes has much to do in determining the particular methods to be used in connection with the housing and the handling of the materials.

Material items, or parts, fundamentally can be divided as follows: Either they are carried in stock or they are not; if they are not carried in stock they are either purchased to order or manufactured to order. The three divisions are sometimes designated as *S*, *P*, or *M*, respectively. The relative magnitudes of these three classes, together with the character of the materials or parts, largely determines what provisions may best be made for the housing and handling technique. Though the variations in these determining elements are many, nevertheless the fundamental principles of good stores-keeping practice are common to them all.

The position occupied by the stores department in the organization, that is, its place as the connecting link between the production, planning, or originating department and the manufacturing departments, makes it essential that the routine work conducted in it be in advance of the manufacturing routine.

It is not good practice to have productive workers coming to the stores department for materials while orders in process wait. The correct procedure is to have the materials for orders prepared in advance and moved into the manufacturing departments on schedule thus creating a forward pressure which tends automatically to urge production forward. This procedure logically makes the stores department a subsidiary under the planning, or originating department rather than under the manufacturing branch of the organization.

Centralized or Decentralized Stores. The locations of storerooms and the relative merits of centralized or decentralized stores depend largely on the nature of the productive processes. It is well to have the materials located conveniently near the manufacturing department concerned so that they may be transferred into production as quickly as possible. If there is to be any natural delay in the handling of the materials it is better to have

that delay occur in the beginning, when the materials are first placed into stores, rather than at the time when the materials are to be released for production.

However, if materials are heavy or bulky, and require special handling equipment, the stores department may have to be located near the receiving department. In such a case the manufacturing department utilizing such materials should be correspondingly located or the materials should be prepared in the stores department so they can be conveniently transferred to the manufacturing department. An illustration of this situation is the case of heavy bar stock, received directly into the stores department which is equipped with cut-off saws. The material is cut for production orders and transferred to the manufacturing department as required.

Factors Influencing Decentralization. In general, parts or materials used by only one manufacturing department are economically located if they are near the department using them. Such considerations as handling equipment, cost of storeskeeping labor or available space may make such an arrangement undesirable. Floor space is most valuable when it is productive. Therefore, as little space as possible should be taken up in the manufacturing departments for storing materials, and the materials which do get into the manufacturing department should all be for live orders, in economic quantities and kept on the move. Furthermore, it not infrequently happens that the storeskeeping activities required by any one manufacturing department are not sufficient to keep one employe efficiently occupied. In such cases, rather than combine the storeskeeping work with work of another character, it is well to centralize the stores and make the custody of them and their handling a specialty.

When it is found to be economical to decentralize some materials, as in the case of rod stock used in an automatic screw machine department, then the materials should be properly housed and protected, and disbursed preferably under the jurisdiction of the stores department. In that way the handling expense will be minimized without weakening the control.

Influence of Types of the Material. While the nature of the productive process has much to do with the problem of stores methods and facilities, the character of the materials themselves is also a determining factor. In general, the materials handled fall into seven classes as follows:

Stock Items.

1. Raw materials.
2. Rough castings.
3. Finished parts or units of materials.
4. Supplies and other expense materials.
5. Finished goods.

Non-stock Items.

6. Purchased-to-order items.
7. Manufactured-to-order items.

The last two of these classes represent items that are procured directly for particular production or shipping orders and therefore should move from the receiving department directly to the locations at which the various items required for these orders are being accumulated. They do not enter into the

regular storeskeeping routine as do the other items in the above list, as will be explained in a later paragraph on stock parts and finished goods.

Influence of Productive Processes. Although the first five of these classes are frequently carried under correspondingly distinct divisions of the inventory, with separate stores records, they may all come together in one store-room with the exception of finished goods, which should be segregated from the others. Bringing all classes of materials to one location often leads to difficulties because some relatively inexpensive parts or materials may move in small quantities to one manufacturing department and in large quantities to another, thus introducing widely different handling costs when requisitions have to be presented for the quantities drawn for each department. What is an economical quantity in one case is not an economical quantity in another case and this has considerable bearing on the centralization of stores.

Influence of Unit Costs and Lot Sizes. The productive, or direct, materials represented by raw materials, rough castings, and finished parts, as above listed, fall into eight categories depending on the relative magnitudes of the unit costs, the quantities in which the materials travel and the quantities in which they are carried in stores. Parts or materials of relatively small unit costs, moving in small quantities but stored in large quantities present a different problem than parts or materials of relatively small unit costs, moving in large quantities and stored in small quantities. This situation often exists in manufacturing plants including widely different types of assembly departments turning out large costly assemblies and small, inexpensive assemblies, yet using common parts.

The eight categories into which productive parts fall are:

1. Small unit cost, traveling in small quantities and stored in small quantities.
2. Small unit cost, traveling in small quantities and stored in large quantities.
3. Small unit cost, traveling in large quantities and stored in small quantities.
4. Small unit cost, traveling in large quantities and stored in large quantities.
5. Large unit cost, traveling in small quantities and stored in small quantities.
6. Large unit cost, traveling in small quantities and stored in large quantities.
7. Large unit cost, traveling in large quantities and stored in small quantities.
8. Large unit cost, traveling in large quantities and stored in large quantities.

If we let c represent the small unit cost, C the larger unit cost, q and Q the small and large quantities in which the parts or materials move into production and s and S the small and large quantities in which the parts or materials are stored, then these eight categories may be briefly represented as follows:

1. cqs .
2. cqS .

3. *cQs.*
4. *cQS.*
5. *Cqs.*
6. *CqS.*
7. *CQs.*
8. *CQS.*

A nut, washer, or stud, for example, used as a fastening part in one assembly department where only half a dozen may be required at a time, and which is stored in small quantities such as a gross, would fall into the *cqs* category. However, if the same part is to be used in another assembly department where it is required in large quantities at a time, then it may become necessary to store the part in large quantities whereupon the part falls into the *cQS* category.

This difference has much to do with the policy of centralizing stores because the law of diminishing returns requires that when the cost of making out a requisition and filling, pricing and posting it, becomes high in proportion to the value of the quantity of material covered by it, then some change should be made in the stores arrangement or methods. Decentralized substores departments may be created, the parts may be carried in small quantities in some productive departments where they are required in small quantities, or as described later under requisitioning according to the particular conditions.

Location Marking and Material Arrangement. Parts and materials used in productive routine are more quickly found and handled if their identification is reduced to code language through the use of a number. This is particularly desirable when the parts or materials are in frequent use, in diversified use or when the demand, as in the case of repair parts, depends upon positive and rapid identification.

The numbers assigned should cover no other function than mere identification of the item and once such an identification number has been assigned, it should not be changed nor should any other number be assigned to the item in another department, as long as the item itself does not change. This is important in connection with repair parts lists which sometimes show items under a series of numbers other than the original identifying numbers and which, therefore, impose the burden of interpretation before an incoming order can be transmitted to the stores department.

This principle applies also to the identifying of locations. Once a location is numbered, that number should not be changed unless some change is made in the location arrangement. In manufacturing practice it is not advisable to identify a location by marking it with the number of the part or the material stored in it. As a general rule the item should carry its own number and the location should bear its own independent number. An exception to this rule may be made in manufacturing establishments in which items purchased for stores, according to specific design, may be assigned identification numbers which correspond to their location numbers. An illustration of this type of item is labels used on rolls of roofing. The form number of the label may be made coincident with the location number without causing confusion in future orders or changes in design.

Types of Locations. Types of locations where materials or parts may be stored are:

1. Yards.
2. Floors.
3. Bays.
4. Stockrooms, storerooms, or vaults.
5. Racks.
6. Bins.

Particularly under centralized stores control, each different location should be identified by a number that should remain permanent as long as the location arrangement remains unchanged and regardless of what kind of material is stored in it. A cross-index should be maintained from which the location of any item may be quickly determined from the identification number of the item.

FIG. 1.—Representative storeroom layout.

As an illustration of good location numbering, the sequence in the number should follow the course of finding the location. First designate the store-room, for example, then the aisle, then the tier, and finally the bin. In Fig. 1 is shown a representative layout for a storeroom with locations numbered on this principle.

Bin Marking. Once having been established, the numbering system should be made uniform in principle throughout the establishment. The rows bins may be numbered and the tiers identified by letters, as illustrated Fig. 2. The letter A should be at the floor level.

Labeling. On the front of each bin, centrally located, there should be placed a bin label immediately above the bin number, this label being marked with the number and name of the part. It is sometimes convenient to

two lines on this label for two identifying numbers. An illustration of this is had in the case of finished parts made from castings which are also carried in stores because other finished parts, slightly different from the first, are also machined from the original casting. The labels for the rough-casting bins, if the castings are stored in bins, may be of a different color from those for

FIG. 2.—Representative tier and bin marking.

the finished-parts bins. Representative bin labels, illustrated in Fig. 3, indicate a finished part, No. *M-589*, which is machined from a rough casting, No. 31,064. The identification number of each of the specific items is featured on the label, the other number being given subordinate prominence.

Appropriate holders for this type of label are available on the market and, if not already on the bin fronts, as they sometimes are in the case of steel bins,

<p>PATTERN NO. 31064 CI</p> <p>DRAWING OR STOCK NO. M-589</p> <p>NAME THRUST COLLAR</p>	<p>PATTERN NO. 31064 CI</p> <p>DRAWING OR STOCK NO. M-589</p> <p>NAME THRUST COLLAR</p>
A	B

FIG. 3.—Representative bin labels. A, rough casting. B, finished part.

they should be permanently attached. The labels, on the other hand, should be made conveniently removable so that in the event of the material being transferred to another location, the corresponding label could be transferred at the same time.

Service and Surplus Stores. Compactness of the active part of a storeroom makes it desirable to limit the amount of material carried in the service bins. In such a case the excess, or surplus stores may be located at another place, away from the field of action. When surplus stores are so carried,

it is good practice to indicate the other location on the label of the service bin so that replenishments may be expeditiously made. If an appreciable number of items are in this category, with surpluses carried elsewhere, then it will be convenient to insert a reversible slip under the bin label. One end of this slip should be plain and the other end marked with a distinguishing color with a space for entering the location number at which the surplus is stored. This device, together with the arrangement of the bin label and holder, is shown in Fig. 4.

Floor Locations. Some materials are more conveniently stored in open floor spaces than in bins and it becomes a more difficult problem to number floor locations. The specific assignment of locations and the numbering of them, however, can be systematically accomplished by stringing wires

FIG. 4.—Bin marking with holder and removable label.

overhead and hanging numbered cards from these wires. Such an arrangement is convenient in paper warehouses in which flat stock is piled high. Posts or other obstructions should be avoided, so that the full floor space will be free for truck movements. In other cases, such as in plants requiring the storage of numerous materials either in containers or in stacks on the floor, an arrangement such as illustrated in

Fig. 5 is convenient. In these cases, the locations are marked in a manner similar to that explained in Fig. 4.

The aisles are numbered and the locations corresponding to the bins are numbered. Thus the location shown in Fig. 5, for example, if it is located in storeroom 63, would be 63-9A3. The location of the material in the bin shown in Fig. 2, if located in storeroom 63, would be 63-5C2, thus preserving the consistency with which locations are specified under the different conditions.

Vertical Stacking. If it is undesirable to store particular rod stock in a horizontal position, or if space limitation leaves insufficient room for the horizontal storing of bar or rod stock such as is used in automatic screw machines, then provision may be made for vertical storing as illustrated in Fig. 6, the location numbering scheme being similar to that illustrated in Fig. 5.

Pipe Frame Racks. For storing long bars, rods, structural shapes, or tubes of sizes that can be moved manually, a rack constructed of pipe framework such as illustrated in Fig. 7 is convenient. The marking may be carried out in accordance with the principle already explained by hanging the label holders vertically where they are out of the way, as indicated to the right of Fig. 7.

Color Code for Steel Bars. When steel bars of different specifications are stored in such a rack the specification is sometimes indicated by color code, the colors being painted on the ends of the bars and rods. If appropriate identification numbers are assigned to the various grades of steel and if the storeroom routine is followed in a systematic manner, this painting of the

ends can be dispensed with. A common source of trouble with such a rack is that no provision is made for taking care of random lengths, or remnants. The rack being entirely open, any remnants that are not long enough to

FIG. 5.—Method of marking floor location of stored material.

span the two adjacent supports fall through. If the pieces are placed somewhere else in the department a clutter of remnants accumulates. It is good practice to shelf in the first space of racks of this kind, as Fig. 7 illustrates.

Heavy Bar Stock. As bar stock gets larger and heavier, necessitating the use of a crane or hoist for handling it, then a fixed rack is no longer applicable. A suitable arrangement may be obtained by the use of wooden spacers which

FIG. 6.—Storing rod stock on end.

FIG. 7.—Pipe framework for horizontal storing.

can be inserted when the bars are placed in the storeroom and removed as the bars are used up. This principle is illustrated in Fig. 8. When large steel bars are stored in this manner it is sometimes found convenient, and a

safe precaution, to indicate the specification of the steel by color code, a stripe of the appropriate color being painted the whole length of the bar.

With stock of this nature it is good practice to locate the cut-off saws in an aisle perpendicular to the bars, thus avoiding the necessity of swinging the bars around while they are suspended from the crane or hoist.

Storeroom Index. It is good practice to have the materials issued to the manufacturing departments by the stores department in accordance with authoritative releases from the production or planning department in the form of some sort of requisition. However, through needs arising in the manufacturing departments, such as spoilage, some materials may have to be requisitioned by shop employees. In order to make it possible for the storekeeper readily to find the material required it is desirable to have an index in the storeroom giving the location of all the parts and materials carried on hand. This may be in book form or card form, frequently loose leaf and with a visible index.

Orderly Piling. Besides being accurate in the disbursement and checking in of materials, the storekeeper should be orderly. Materials or parts should be neatly arranged and the whole appearance of the stores department should have an atmosphere of orderly control. Various kinds of parts may have to be stacked in different ways and a little ingenuity on the part of the storekeeper will reveal the most desirable way of stacking even complicated parts.

In Fig. 9 there are shown two incorrect ways of piling pedestal bearings and a correct way. By applying the proper means in such cases floor space can be conserved and the stores department given an orderly appearance.

Unit Piling. Handling and storing of parts, or material items, in standard unit lots is often economical. It is a particularly economical practice when the unit quantity can be processed through the manufacturing departments and into stores intact. Special trays may be convenient as illustrated in Fig. 10.

Heavy material, such as flat paper stock, may be economically handled if standard quantities are strapped onto inexpensive skids. The whole unit may be handled into and out of freight cars and warehouses with facility.

Similarly standard quantities of lumber may be stored on platforms the wheels of which rest on rails. The whole unit may be drawn into the kiln by tractor and thence to the mill.

Stock Parts and Finished Goods. Finished goods should be identified by catalogue numbers and parts should be identified by drawing numbers, if manufactured, or by stock numbers if they are purchased for stores. If

FIG. 8.—Horizontal storing of heavy bar stock.

FIG. 9.—Correct and incorrect methods of piling pedestal bearings.

FIG. 10.—Trays for standard unit lots.

parts are purchased only as required for a particular order, they need not necessarily be given a number of any kind. These two classes of items, namely, finished goods and finished parts, are tied together by material lists. This list is of vital importance in connection with the mechanism of production control in establishments involving assembly and care should be exercised in making it of appropriate design adequately to serve this function.

As mentioned in a previous paragraph, there are three classes of parts entering into assemblies:

S parts, which are carried in stores.

P parts, which are purchased directly as required.

M parts, which are manufactured only as required.

FIG. 11.—Storing of finished parts ready for assembly.

Thus when a finished device is to be produced, it is necessary to obtain some parts from stores, to issue purchase orders for others and to issue individual manufacturing orders for still other parts. Indication of which class each of the parts falls into is made on the material list, but there must be provided in addition to this, some systematic means of accumulating the various classes of parts so as to minimize the attention that must be given to getting all the necessary items together quickly and as automatically as possible.

Control of Parts for Assembly. Therefore, in the finished parts stockroom, or in a properly protected enclosure in the assembly department, there should be provided an arrangement such as is illustrated in Fig. 11. At this location

there should be hung a copy of the material list so that the different classes of items may be checked off as they arrive from the receiving department, stores department or from the various manufacturing departments. All of the classes of parts should be routed directly to the accumulation stall assigned to the particular job on which they apply, thus bringing the items together automatically.

Platforms for lift trucks may be used to advantage for the major parts and a shelf may be provided for the minor parts with tote boxes to receive them and to minimize handling. When the items on the list are all checked off, the job is ready for the assembly floor.

It usually happens that not all of the parts have been received up to the time when the job is scheduled to be delivered to the assembly floor. The storekeeper should watch this and he should be in a position to follow up on delayed items. For this purpose a schedule board is of advantage. This may be simply a blackboard with columns as shown in Fig. 12. Each

ASSEMBLY ORDER NO	LOCATION	DATE TO DELIVER	OUT
E-5701	5 A 3	$\frac{1}{2}$	$\frac{1}{2}$
E-5705	4 A 1	$\frac{1}{2}$	

FIG. 12.—Finished-parts assembly schedule board.

assembly or erecting order number is registered as soon as the material list is received in the finished stock department, or in the enclosure in the assembly department. The location number of the accumulation stall where the parts are to be gathered and the date when the materials are to be delivered to the assembly floor. Two or three days in advance of this wanted date the storeskeeper should glance over the material list in order to note any missing items and get in touch with the production office, or planning department with a view to obtaining the items needed. If the practice is in effect of making advance deductions of stock parts from the stores record in the office, then the storeskeeper need not necessarily gather up the *S* items shown on the material list until it is about time for the job to be sent to the assembly department.

It is important to have these accumulation stalls protected by having them enclosed. Otherwise when the assembly department starts to work on a job it may find numerous parts missing because of having been "robbed" for other jobs or taken to replace parts spoiled.

The finished goods should be kept in a stockroom as convenient to the shipping department as possible. Locations should be marked in accordance with the foregoing principles and a record of the products in stock should be carried in the production or planning office so that incoming orders for stocked products may be deducted from the stock record and dispatched immediately to the shipping department for shipment from stock.

Requisitioning and Delivery. When materials or parts are transferred from the stores department to a manufacturing department, the requisition, which furnishes the authority for the transfer, has to perform more than the simple function of drawing the material. The requisition is also the medium from which a deduction is made on the stores record and from which the cost department makes the financial transfer from the inventory account to work in process and to the job cost. That is, the requisition is not only the authority for delivering material but it also is the basis of clerical transactions.

The expense involved in the clerical work is usually charged to overhead expense and therefore if there is a needlessly high number of requisitions flowing into the office from the storerooms and if the values represented by the requisitions are small, the overhead expense will be needlessly high.

Furthermore, there are manufacturing processes such as molding of composition parts, for which the production orders call for large quantities to be produced day by day over a considerable time. Material has to be drawn from fresh quantities which are prepared day by day and therefore, in the course of completing the production order, a large number of requisitions may be turned in for material applying on a single production order, each calling for relatively small quantity with the small quantities varying. These large numbers of requisitions have to be added together in order to arrive at the total amount of material consumed on the production order to which they apply and the clerical work entailed may be considerable. Furthermore, if there turns out to be any discrepancy between the total amount of material shown on the requisitions and the standard amount that the production order should have required, there is no way of making a satisfactory reconciliation. It is usually too late to make a check-up or investigation and the custom is simply to charge whatever the requisitions call for.

Then there are the small-cost parts and materials which move in small quantities into production. To have to make out a requisition for small values of this kind involves a handling and clerical expense that may be badly out of proportion to the value of the materials covered by them.

"Drawing" or "Issuing" Materials. These are some of the conditions that determine the proper basis for drawing or issuing materials from stores. If production orders are issued to the manufacturing departments and the necessary materials then requisitioned, that means drawing material from stores. On the other hand, if the production orders are prepared in the production or planning office, the material figured or copied from a material-standard record, and then issued to the stores department on the way to the manufacturing department, then the stores department prepared the material in advance of the receipt of the order by the manufacturing department and that is issuing material from stores. In so far as possible, all movements in the productive process should be forward movements. That is to say,

in a manufacturing plant it is usually the better practice to issue materials than to draw them.

The distinction may be illustrated in two ways, and these two ways have much to do with the determination of what is best practice in requisitioning materials.

Planning Requirements in the Shop. The first of these two ways is for the production office to prepare production orders and issue them immediately to the manufacturing departments. The production office may even go so

FIG. 13.—Orders transmitted to shop for preparation.

far as to make an advance deduction from the stores record or perpetual inventory record without identifying the entry thus made on the stores record with the particular production order. When the manufacturing departments are in a position to start work on an order, they may proceed to requisition the necessary materials, writing out a requisition in at least one copy and presenting it to the storeskeeper. All of the production orders, under this condition, are in the manufacturing departments where they are sorted out and planned. The situation is represented in Fig. 13.

FIG. 14.—Orders prepared in advance for the shop.

If the situation is like this, then the materials are drawn from stores.

Planning Requirements in the Office. The second method is to provide for the material requirements in the office, retain the orders in the office until they are scheduled to be worked on in the shop and then transmit them to the stores department where the materials are prepared and delivered to the shop with the orders. For comparison, this situation is represented in Fig. 14.

In the latter case the materials are issued from stores. These two opposite situations make considerable difference in the storeskeeping routine. The second is usually the more desirable plan for a factory because it puts the urge in the forward direction by transmitting to the shop fully planned orders ready to be executed.

Before explaining the requisitioning procedure for this second situation it will be desirable to view the two methods from the standpoint of stores control. Strict accounting procedure would require that a requisition, just as a bank cheque, should be presented before the material is withdrawn from stores and that this requisition should not be deducted from the stores record until after the material has been delivered. This would mean that the stores record will always be lagging behind the movements of material thereby becoming a historical record of past transactions and therefore not constitut-

FIG. 15.—Comparison of stores control methods. A, the draw method. B, the issue method.

ing an element in the control of materials. The bin will become empty before the stores record shows none on hand and shortages will inevitably result and probably necessitate the expense of "shortage chasers" in the shop.

Comparison between Draw and Issue Methods. The opposite situation to this is the one wherein the stores record is placed in advance of the actual movement of material by making the deduction from it before the material is actually delivered from stores. In this case the stores record will show none on hand some time in advance of the time when the bin actually becomes empty and this advance warning may be sufficient to avoid actual shortages, thereby placing the stores record in a control position.

A comparison of the two plans is shown in Fig. 15.

In so far as storeskeeping has to do with productive materials, it is usually advisable to include as many items as possible under the so-called issue method, making a deduction from the stores record before the material is actually removed from the bin or location. If the unfilled requisitions are

handled systematically, being kept together in the storeroom until they are filled, then it would not be difficult to reconcile the bin count with the balance shown on the stores record. All that would be necessary is to add up the unfilled requisitions for each item and deduct the total from the quantity in the bin, then the remainder should agree with the balance shown on the stores record.

Reconciliation of Stores Records. Requisitions are not always necessary for productive material. Production orders or material lists may take their place as will be explained in a later paragraph. However, whatever form the medium may take, the principle is the same in making this reconciliation.

Form 94	BIN CHECK		DATE _____
DWG. OR STK. NO. <u>X-531</u>	PART <u>Shaft</u>	MATL <u>Steel</u>	
STOCKROOM <u>63</u>	LOCATION <u>16 F 4</u>		
A QUANTITY IN STOCKROOM BIN OR LOCATION	<u>20</u>		
B QUANTITY ON UNFILLED REQNS. & M.L.S IN STOCKROOM	<u>4</u>		
C QUANTITY ON UNFILLED REQNS. & M.L.S. IN OFFICE ALREADY POSTED	<u>3</u>		
D QUANTITY THAT SHOULD APPEAR ON STORES RECORD A-B-C	<u>13</u>		
<u>C.H.</u> STORES RECORD	<u>a m.</u> BIN COUNT BY		

FIG. 16.

It is good practice to check the bin counts at least once a year, or oftener, if necessary, in order to keep the counts and the balances shown on the stores records in agreement. If they are kept in agreement by such a plan, then it would not be necessary to take a physical inventory at the end of the year.

A convenient reconciliation slip for use under the issue method above described is shown in Fig. 16.

When Productive Material Requisitions Are Economical. Material requirements may be indicated directly on the production order or, in the case of materials required for assemblies, the requirements may be enumerated on material lists. In either case it is not necessary to copy these requirements onto requisitions unless one of the following conditions exists:

1. That an appreciable percentage of the items called for on the production orders or material lists going through in any one day are repeated on several of the orders or lists.

2. That an appreciable percentage of the items on each list are repeated frequently in that list.

3. That the part numbers, or material stock numbers shown on the material lists do not fall in any sequence.

Under any of these conditions it may be economical to copy the requirements onto requisitions so they can be sorted for posting to the stores record. The repetition should be sufficiently frequent so that the cost of preparing and sorting the requisitions will be offset by the convenience afforded in the operation of posting.

Convenient Form of Requisition. When requisitions are used, it is well to have one color for supplies, or expense materials, and another for productive material, since the former have to be charged to overhead expense and the latter to the costs. A convenient form of requisition, when prepared by hand rather than by Fanfold typing, is shown in Fig. 17.

57 DATE	1 1/4" Bl. Cup		2505-17 N DRG. OR STK. NO.	Be. MATL.
63 STCKR'N	6 C 18 LOCATION		2 QUANTITY	- PATTERN NO.
55 TO DEPT		13¢ UNIT COST	26¢ AMOUNT	3509 ORDER NO. OR ACCOUNT
REMARKS				
STORES REQUISITION FOR ALL PRODUCTIVE MATERIAL FOR REQUISITIONING SUPPLIES USE YELLOW FORM				
Form No. 16			SIGNED <i>F. H.</i>	

FIG. 17.

The convenience of this arrangement lies in the natural sequence for the storeskeeper who first reads the item, then the identifying number, then the location and finally the quantity required, and for the cost clerk who finds the quantity and price near together and, when the extension is made, finds the amount adjacent to the order number or account number to which the charge is to be made.

These requisitions are evidences of the transfer of values. It involves time and expense to make them out and handle them. Therefore, the value covered by the requisition has a bearing on the economy of their use. It is not advisable to make out a requisition costing 2 cents in order to obtain an item which in itself costs only 1 cent. This fact is one of the important considerations in the question of decentralized stores of small parts or inexpensive materials, and in the question of what form the requisition should take in order to be of economic value.

Special Forms of Requisitions. In the case of large production orders, which may run over several days or weeks, and requiring material that cannot be completely issued all at one time either because of space limitations, convenience, or deterioration, it would not be economical to write out a requisition every time a batch of materials were required for the day's work. Numerous requisitions would pile up against the order and entail considerable clerical work in order to sort them, total them, make the extension and compare their total quantity with the standard quantity initially specified for the job. Furthermore, in case the total of the requisitions varied conspicuously from the initial standard, it would be exceedingly difficult to effect a reconciliation.

60	60	60	60	60	60	60	60	60	60	60	60	60	60	60	60	60	60	60	60	60	60	60	60	60					
30	30	30	30	30	30	30	30	30	30	30	30	30	30	30	30	30	30	30	30	30	30	30	30	30					
●	●	●	●	●	●	●	●	●	●	●	●	●	●	●	●	●	●	●	●	●	●	●	●	●					
25161					591					300					450					600									

FIG. 18.

In such cases a special form of requisition may be found convenient, such as shown in Fig. 18. When a blanket requisition of this type is used, the total material requirements are figured in advance and marked off on the form as indicated at 420 pounds in this case.

Each day, as the worker is furnished material in convenient, and uniform lots, the quantity is indicated on this form by merely punching out the quantity with a conductor's punch as illustrated. As this punching out continues day by day, the limit mark is finally reached, thus automatically stopping the issuance of material against the particular job. Should it happen that the job is not yet finished, and more material is required than was thus provided for, an investigation can be made at the time to determine whether the initial material calculation was wrong or whether the material was not used economically.

Similar forms are convenient in connection with material issued to automatic screw machine departments in which it is not desirable or convenient to keep a large quantity of material on the floor. If a deduction has been made in advance from the stores record of the amount marked off on such a blanket requisition, and if it becomes necessary to increase the amount of material thus provided for on account of the initial material calculation having been in error, or there having been a variation in the weight of the material itself, then a special requisition for the excess should be prepared so that the stores record may again be posted in order to cover this excess. If the excess results from spoilage, then a regular spoilage ticket should come through and this should be the authority for the issuance of the extra amount of material.

Use of Consistent Units. An illustration of conditions under which an excess often has to be issued on account of the material standard having been wrong is had in the case of such material as sheet fibre. The fibre is purchased by the pound, issued by the pound, but may be used for making punchings which are governed by square inches. Unless the fibre always weighs the same, per square inch, then there will be a discrepancy, because 100 pounds in one lot will not yield as many square inches as in another lot. When the number of pieces to be produced has to fit into a production control plan, and therefore be of importance in providing a balanced quantity of parts, it will be desirable to translate the pounds into square inches, or square feet, when the newly received sheet stock is put into stores, and the stores record set up in terms of the surface measure.

Weighing Clerical Cost against Value of Requisitions. In case there are small parts, or inexpensive materials, called for in a material list for a job, and along with these relatively small-cost items there are others of relatively large cost, as is usually the case, then some attention should be given to the law of diminishing returns in the preparation of requisitions. It would not be advisable to make out many requisitions for items which cost only one or two cents each if the cost of handling the requisition were two cents or five cents. Some line of distinction should be drawn between the items for which requisitions are economical and those for which they are not economical. It is a balance between the cost of handling a requisition and the value covered by that requisition. That is, if a small-unit cost item be represented by c , and the small quantity in which it moves into production be represented by q , then the value covered by the requisition would be

$$v = cq.$$

Unless the cost of handling the requisition is small in comparison with this value, then requisitioning, in the usual manner, is not economical. The cost of a requisition, in per cent of the value covered by the requisition, runs up rapidly as the value of the requisition decreases.

If R = the cost of making out and handling one requisition,

p = the per cent which this is of the value covered by the requisition,

c = the cost of a small-unit-cost item,

q = the small quantity in which the item moves into production,

then
$$R = pcq \text{ or } p = \frac{R}{cq}$$

If the unit cost of an item is relatively large, as represented by C , and the item moves into production in relatively large quantities, as represented by Q , then the same equation holds, with the corresponding symbols, that is

$$p = \frac{R}{CQ}$$

It will be evident that as the value cq increases toward the larger value CQ , the percentage cost per requisition will decrease or, as the value covered by the requisition decreases, the percentage cost of preparing and handling a requisition will increase.

With the use of the equations it will not be difficult to determine what should be the maximum allowable cost per requisition in proportion to the value covered, or what should be the minimum value for which the writing of requisitions should be permissible.

Alternative to Requisitioning. As previously stated, some other way should be found for obtaining small-cost, small-quantity parts and materials than by requisitioning. Part of the question lies in a consideration of what degree of precision is required in the costing operation. It might be quite satisfactory simply to use the parts without any requisition whatever, provided there is no need for knowing to what extent the costs may be upset by such practice. However, with due regard for costs and for convenience in obtaining such items the methods open to choice for avoiding requisitioning are as follows:

1. The items may be classed as supplies, or expense materials, requisitioned in economic quantities into the productive departments and there used freely as required in the same way such items as paint would be used.

2. For each assembly requiring such items there could be established a standard percentage for these items and they could be put into the costs by adding this percentage to the total cost of the other items, a service supply of the items being carried in the manufacturing department.

3. The total of all small items could be drawn out in economic quantities, charged to a special deferred account and this account liquidated into the overhead expense each month in a manner similar to that for handling depreciation charges.

4. They might be ignored altogether as being of relatively small importance.

5. For assemblies, all of the small items might be made up into standard packages, given a stock number, and handled as one unit for assembly jobs.

The selection of the most satisfactory method to use will depend upon the particular nature of the manufacturing process and the particular conditions existing.

CHAPTER I

THE FIELD OF OFFICE MANAGEMENT

By M. B. FOLSOM, *Assistant Treasurer, Eastman Kodak Company*

This outline of office management contains sixteen general subdivisions as follows (see Fig. 1):

- Building.
- Furniture and equipment.
- Office appliances.
- Stationery and forms.
- Personnel.
- Job analysis.
- Salary standardization.
- Correspondence.
- Stenography and typing.
- Mailing.
- Filing.
- Intercommunication.
- Organization.
- Departmental expense statements.
- Office methods and routine.
- Measurement and control of output.

In order to function efficiently an office manager should touch upon every one of these phases of work. One cannot say that one is any more important than the others. Each one should be covered and they are all interdependent.

Under the various headings we have:

Building.

- Efficient floor layouts.
- Lighting, daylight and artificial.
- Heating and ventilation.
- Reduction of noise.
- Locker rooms.
- Toilet facilities.
- Drinking fountains.
- Elevators.
- Planning for expansion.
- Maintenance.
- Materials handling equipment.
- Safety.

FIG 1

Efficient floor layouts and planning for expansion are two of the most important functions in regard to the building that the office manager has to face. It is a general rule for offices to increase in size, and if some definite plan is worked out to cover the expansion for a few years ahead, there will be less confusion and inconvenience when the increase comes.

Furniture and Equipment.

Standardization of

Desks.

Chairs.

Tables.

Filing cabinets.

Vaults and safes.

Control of purchases.

Office Appliances.

Standardization of

Approval of requisitions for

Maintenance of

New uses for

Adding machines.

Billing machines.

Bookkeeping machines.

Calculating machines.

Dictating machines.

Duplicating machines.

Mailing machines.

Typewriters.

Miscellaneous machines.

Office appliances.

As a general rule we depend upon salesmen to present to us new uses for their machines, but often the salesmen are not familiar with the work being done in the various departments. The office manager should, therefore, keep in close touch with the new machines that are brought out, and by means of periodic surveys of the routines in the departments ascertain whether there are uses for these machines or new uses for the older type of machine.

Stationery and Forms.

Standardization of forms:

1. Size.

2. Typography.

3. Paper.

4. Color.

Standardization of supplies:

1. Grade or kind.

2. Quantity to order.

Control of purchases and disbursements:

1. Stationery.

2. Supplies.

Several companies have been able to make a distinct saving by making a thorough survey of stationery and forms. In many cases more expensive

forms are being used than are necessary and savings will result also from standardization.¹

Personnel.

- Approval of requisitions.
- Tests.
- Hiring.
- Office manual.
- Follow-up of new employees.
- Records of progress.
- Promotions.
- Misfits.
- Vacations.
- Training.
- Educational courses.
- Rating cards.
- Tardiness.
- Absenteeism.
- Interviewing employees leaving.
- Grievances.
- Analysis of turnover.
 1. By departments.
 2. By causes.
- Office hours.
- Recreation facilities.
- Lunch room.

Job Analysis.

- Analysis of positions by department.
- Analysis to be used for
 1. Salary standardization.
 2. Specifications for personnel department.
 3. Instructions for new employees.
 4. Lines of promotion.

Salary Standardization.

- Limits of specified jobs.
- Comparisons with salaries of other concerns.
- Premium systems.
- Premium or bonus systems are being quite generally used for the following jobs:
 - Typing.
 - Dictating-machine transcription.
 - Tabulating.
 - Billing.
 - Posting.
 - Addressograph operating.

In some offices the premium or bonus system has been extended to other jobs, but progress in this direction has until recently been slow.

¹ See Chap. VII, Forms: Their Design and Use.

Correspondence.

- Manual for dictators.
- Other methods for improving correspondence.
- Uniformity.
- Form letters for routine correspondence.

The general practice now in use for improving correspondence seems to be to issue a series of booklets for the dictators. Each booklet is concise and deals with only one phase of the general subject.

Stenography and Typing.

- Centralization.
- Use of dictating machines.
- Manuals.

Mailing.

- Centralization.
- Reading and distribution of incoming mail.
- Dispatch of outgoing mail.
- Telegrams and cables.

Filing.

- Centralization.
- Storage of records.
- Destruction of records.

As records gradually accumulate, the question of destruction of records becomes of increasing importance. In our case, we have reached the point where we have to destroy some of our old records or increase the size of our vaults. We have made a survey of all our records, listed them by departments and have obtained a decision from the department head, the Accounting Department and the Legal Department as to the length of time each record should be kept. We have found that it is useless to keep many of these old records and we know exactly how long each record should be kept.

Intercommunication.

- Messenger service.
- Pneumatic tubes.
- Telephones.
- Teletype.
- Telautograph.
- Buzzers.

Organization.

- Organisation charts of departments.
- Functions of departments.
- Supervision of departments.

It is well to have organization charts not only of the office as a whole but also of the individual departments.

Departmental Expense Statements.

- Salaries.
- Stationery and supplies.
- Overhead.
- Budgets.

Office Methods and Routine.

- Suggestions for changes.
- Approval of changes.
- Follow-up of complaints and errors.
- Department manuals.
- Flow of work.

Periodic Departmental Surveys by Some One with a Perspective. In order to keep the office routine on an efficient basis, it is necessary that periodic surveys be made of the individual departments. The survey should be made by someone outside of the department who can bring a different viewpoint into the work. After the survey has been completed, recommendations, if any, are submitted to the department head for his approval or disapproval.

Measurement and Control of Output.

- Records of individual outputs.
- Records of department outputs.
- Standards.
- Planning.
- Scheduling.
- Handling and reducing peaks.

In keeping the records of individual and departmental outputs, it has been found valuable to use graphic charts. The information can be presented to the department heads in a more striking form by the use of charts.

CHAPTER II

PHYSICAL FACTORS

HOUSING BUSINESS ORGANIZATIONS FOR EFFICIENT OPERATION¹

BY HARRY ARTHUR HOFF, *H. A. Hoff and Company*

In the past two decades the factor of rapidly increasing size has become an outstanding characteristic of American business organizations. This factor has made its influence felt to such an extent that special housing problems have forced themselves upon the consideration of business executives and they have been compelled to seek solutions mainly by the trial and error method; needless to say, the solutions arrived at in this manner have not always satisfied the needs.

With increasing size of business organizations we usually find as concomitants the development of functionalization, specialization and mass production, accompanied by mechanization of work and standardization of equipment. These increasingly complex conditions, in turn, create special operating requirements which have an important influence on housing considerations. Among the requirements which must be taken into account in planning the physical setting to be provided for the performance of work are these:

1. Need for more effective organization and control.
2. Need for increased accuracy and dispatch in connection with routine operations.
3. Need for better adjustability of space to operating requirements.
4. Necessity for achieving higher standards of illumination, ventilation, acoustics, and other physiological factors.
5. Introduction of mechanical intercommunicating devices.
6. Suitable location of centralized suites for executives, as well as of offices for department heads.
7. Proper location of vaults, storage rooms, and supply departments.
8. Provision of adequate service elements.
9. Provision of adequate facilities for reception of public.
10. Provision of adequate facilities for receiving, storage, shipping, etc.
11. Adaptability of space to varying rates of departmental growth.
12. Maintenance of sound balance between horizontal and vertical expansion.

¹ An address delivered before the Chicago chapter of the American Institute of Architects and published by *The Architectural Forum*, April and May, 1930.

The architect who is faced with the problem of bringing to expression in a building which he has been commissioned to plan, a logical and comprehensive scheme of utilization which will meet the needs just mentioned, together with many other needs of related character, often finds himself hampered from the very beginning of his study by the fact that, as a rule, the client either does not know his own operating requirements or is unable to express them in terms which the architect can understand. Furthermore, it is frequently the case that the client has committed himself to the purchase of a site without consultation with those competent to advise him, and thus, regardless of operating requirements, the possibilities open to the architect are sharply limited by the fixed conditions.

For the purposes of the present discussion let us accept as a postulate the principle that in all building planning, and particularly in the case of a special purpose office building intended for exclusive occupancy by one organization, the proper point of departure is a study of the organization and its requirements. I shall endeavor to outline the major elements in a practical program covering a special purpose office building project and, against such a background, to describe briefly the specific manner in which the physical conditions of the building must be adapted to operating requirements.

Operating Requirements and Their Effect on Planning. Assuming that a business organization is about to embark upon a new building project, the first practical step to be taken is to ascertain the effect of its operating requirements on the planning of the structure. In order to secure the basic facts, a study of departmental organization should be undertaken and a statement prepared giving the names of the various operating units, together with comprehensive descriptions of the functions performed by each. With such a statement available, the next step is to identify all the departments particularly concerned with service to the public, for it is obviously necessary to give such departments preferential locations so as to facilitate their contacts with the public.

Having determined in a preliminary way the manner in which outside contacts are to be maintained, the next step is to ascertain in a tentative manner the desirable physical grouping and location of operating units, based upon:

1. Character of supervision required.
2. Related nature of work.
3. Frequency of personal intercommunication.
4. Proximity of supervising officials.

The influences on space planning exerted by these four factors often prove to be of conflicting character. It therefore becomes a nice problem to determine which of the four factors shall be given the most weight and how reconciliation of differences may be achieved. Unless the problems involved in departmental location and layouts are solved from the broad point of view of benefit to the whole, it will be impossible to avoid costly changes and alterations after the organization is housed in the new building.

Mechanization of Work. One of the outstanding characteristics of modern management is the trend toward mechanization of work. The increasing

need for accuracy and speed occasioned by the exacting demands of business makes it impossible to continue to achieve satisfactory results through the application of human energy alone. Consequently, in the last decade or two, we have witnessed enormous developments in the field of office machinery and the subordination of office procedures and systems to the possibilities presented by the use of standardized machinery.

The introduction of such machinery has, perforce, had an influence over the provision of space and the modification of space standards, as well as over the augmentation of wiring services, far beyond anything which could have been imagined ten years ago. It has, moreover, brought about the necessity of installing acoustical treatment so as to reduce to a minimum the strain upon the nervous systems of workers caused by the noise of machine operation. To be convinced of the profound influence of the trend toward mechanization of office work upon the physical conditions of the environment in which the work has to be performed, one has only to make a comparison between the characteristics of the modern-day office building and those of the office building of ten or fifteen years ago.

Intercommunication. Among the more important operating requirements, viewed from the effect upon office planning, may be mentioned the need for more rapid performance of work and more expeditious intercommunication. The pace of business today is far faster than it was ten years ago. Whatever the cause for this condition, modern office planning must take account of it as a factor of the highest importance. In practice, the solution of the problem of accelerated activity is predicated upon the effective location of operating units in both the horizontal and vertical relationships and the provision of mechanical and electrical intercommunicating devices which overcome distance and which dispatch messages and papers at a rate of speed far exceeding the highest standard possible of attainment by human means.

Departmental Space. Another factor linked with operating requirements is the determination of departmental space standards and of the varying rates of growth experienced by different departments of the organization, so that adequate provision of space may be made for both present and future needs and the twin dangers of scanty or over-liberal space allowances may be guarded against. The importance of determining accurate space standards cannot be too strongly stressed, and this task should be approached by established techniques which have been devised for determining net areas required.

In a large bank whose rapid growth had necessitated the occupancy of several buildings in the financial district of an eastern city, it required a period of nearly three months of painstakingly careful analysis and study to measure present and prospective space requirements preparatory to planning a new bank building. The study was undertaken by trained engineers in the employ of the bank planning committee, and every single element entering into the detailed space calculations was checked back with the department heads concerned before the definitive space schedules covering existing requirements were ultimately compiled. After this had been done, the engineers prepared estimates of the personnel and equipment requirements as of the

approximate time of completion of the new building and for a period of five years thereafter, and from these they finally determined the probable space requirements for the same dates.

It will readily be seen from the foregoing discussion of operating requirements and their effect upon planning, that studies along the several lines indicated are essential in order to provide the owner and architect with information of valid and detailed character for the purpose of undertaking a new building program on a sound basis. Unless the influence of operating requirements over building planning is thoroughly recognized and its implications are pursued to logical limits, the success of any new building program will be open to question.

Determining the Character of the Building. After operating requirements have been ascertained, the next practical step involves the determination of the character of the building which is to be erected. Eliminating from discussion the subject of building regulations—which differ in various parts of the country—we may proceed to a consideration of the questions of size and general proportions. Both of these usually present interesting and many-sided problems. We will assume that, although the question of financial investment is naturally an important one, organizations whose affairs justify housing in a special building are usually in a position, within reasonable limits, to subordinate problems of building finance to other practical considerations. As a rule such organizations are governed by the desire to erect rather monumental buildings and at the same time to provide suitable space to meet their requirements for an indefinite period of years.

In the past, however, it has frequently happened that business organizations such as banks, insurance companies and important commercial and industrial concerns which have planned more or less elaborate buildings, have failed adequately to forecast their space requirements. Consequently, within a brief period of years of occupancy of the new offices, they have found that their quarters were becoming crowded and have been compelled either to increase the density of space occupancy or to add in makeshift fashion to the existing buildings. In recognition of this situation the pendulum has now swung in the opposite direction, and a tendency has developed to erect buildings larger than are warranted by reasonable estimates of future space requirements. This condition has caused the adoption of extravagant space standards, the tying up of capital in unproductive investment and excessive maintenance costs.

Factor of Organization. It should be recognized at the outset that the factor of organization has an important bearing upon size and proportions of the building. Most businesses will find, after study of their organization characteristics, that there are relatively few major functions to be performed. As a rule these embrace, specifically, finance, production, distribution, accounting, engineering and service. Properly to integrate these functions, it is often found advisable to locate the departments responsible for their performance on different floors of the building, or at least to group them on three or four levels. Such an arrangement obviates the creation of conflicts due to the demand for additional space caused by varying rates of departmental growth. The functions named are hardly ever found to require

areas of like size, and proper grouping usually makes it possible to provide for their future growth by means of horizontal expansion.

From the foregoing considerations, it appears that the practice of estimating space requirements for many years in advance need no longer be followed and that the problem of size resolves itself into finding the practical answer not to the query, "How big a building shall we build?" but rather to the question, "How small a structure will reasonably meet operating requirements for a limited period of time?" When the need for additional space evidences itself, this may be provided by the erection of wings attached to the first unit, and this procedure may be continued until the optimum size of the building, taking into account design and mechanical facilities, as well as limitation of the plot of land upon which the structure is erected, has been reached.

It is essential, of course, in considering size and general proportions of the building, to study carefully such questions as ceiling heights, elevators, exposure to light and air, location of fixed service elements, number of subterranean levels and introduction of special features such as vaults, storage rooms, building service units, etc.

Horizontal and Vertical Expansion. For every organization it becomes necessary sooner or later to determine and maintain a balance between horizontal and vertical expansion. If the building is so designed as to violate permissible limits in either of these directions, it may be assumed with certainty that excessive operating costs, insofar as staff and equipment are concerned, will be experienced. In one instance, the office layout which had been planned resulted in separating, by a distance of about 240 feet in the horizontal direction, two important groups of executives, the character of whose activities necessitated constant personal contacts. When this defect was pointed out to the organization, the validity of the criticism was admitted but the conclusion was expressed that nothing could be done about it since all arrangements had already been consummated.

It remained for the engineer whose advice had been sought with respect to the space problem, to make the obvious suggestion that the organization arrange to exchange one-half of the space on the floor in question for an equal area on the next floor above, in direct vertical relationship to the half floor to be retained. This plan was finally adopted, a separate stairway connecting the two floors was introduced and the two groups of executives found themselves located within fifteen feet of each other in the vertical direction. Easy communication was, of course, furnished by the stairway, and the result of the change was to facilitate extremely important contacts of constant occurrence throughout the business day and thus to save a substantial expenditure of time, money and energy.

Ceiling Heights. In considering further the problems of size and general proportions of the building, a factor of great importance is the provision of adequate ceiling heights. The modern trend in planning offices is entirely in the direction of the application of the open office principle. No longer are clerical staffs separated from each other by partitioned spaces which obstruct the flow of the work and foster the *departmental* instead of the *organization* viewpoint. In the well planned office, groups of clerical workers are brought

together in large, open, unobstructed areas which strengthen *esprit de corps* and permit of planning for expeditious procedure according to the principle of forward movement of work. For such offices, ceiling heights of more than the usual commercial standards must be provided.

One defect of the commercial type of office building for planning large areas to be occupied by scores if not hundreds of clerks, lies in the fact that, with standard ceiling heights of ten feet or thereabouts, the provision of adequate artificial illumination at desk level brings the remote fixtures into the line of vision of clerks and thus creates an unsatisfactory lighting condition. Moreover, from the psychological point of view, a relatively low ceiling height in a large open office causes an unpleasant sense of space restriction and consequently has an adverse effect upon the desire of employes to work. For these reasons and others which might be mentioned, ceiling heights of buildings designed in accordance with the requirements of large clerical organizations should be at least eleven to twelve feet in the clear; the extra cost involved in supplying this feature is, according to experience, more than offset by its favorable influence upon work productivity.

Light and Air. Considering now the questions of exposure to light and air, it is essential in order to capitalize the relatively large investment constituted by the annual payroll of a clerical organization, to provide good conditions of illumination and ventilation. Therefore, in determining the problems of size and general proportions, we must bear in mind that, until such time as dependence may be placed entirely on artificial illumination, fenestration should approach 50 per cent of the total wall space, and wings should, as a rule, not exceed fifty feet in width. If these two standards are adhered to, one may be assured that the clerical staffs to be housed in the building will, for the major portion of the business day, enjoy natural illumination and the most favorable conditions of ventilation which can be provided in the absence of an artificial system, to which specific reference will be made later.

Architectural and Work Objectives. As far as design of a special purpose office building is concerned, it may be permitted to a layman to venture the opinion that it should be characterized by simplicity, individuality and impressiveness. In general, business organizations which contemplate the erection of an office building for their own occupancy, are likely to consider first of all the architectural elements of the problem. With the highest possible regard for the importance of these elements, it should be recognized that the prime purpose of erection of a building of the type described is to further the work objectives of those whom the building is intended to house. Physical environment exercises a tremendous influence over productivity, and the first and last problems of all special purpose building planning should be concerned with the creation of conditions which will be conducive to the achievement of a decrease in operating costs.

Many years of experience in dealing with problems involved in special purpose building planning justify the opinion that the difference in work accomplishments between an organization located in a poorly planned, badly lighted and crowded office and one housed in a building which brings to expression the results of purposeful planning, based upon intelligent analysis

and adherence to high standards, amounts usually to an increase of from 15 to 25 per cent in the productivity of the staff. Translated into terms more readily understood, this means that the increase in staff productivity is often sufficiently great to exceed the interest on the complete investment required to finance the cost of the new building.

From the foregoing discussion, the conclusion is justified that the determination of the character of the building must be based upon elements such as those referred to and that a definite relationship may be worked out between the needs of the organization and the characteristics of the building which is to house it. It should be especially noted at this point that careful study of all the factors to which reference has been made should logically precede the architectural planning stage. Unfortunately, this consideration is honored more in the breach than in the observance, with the result that the burden of responsibility of the architect, in any case great, is needlessly augmented, and a series of delays, compromises and adjustments of conflicting viewpoints complicates the creative period of his work. The majority of architects who have had experience in the planning of special purpose buildings have learned to their cost how discouraging and detrimental such a condition can be. It is therefore regrettable that architects, as a rule, are without influence in the shaping of the program which should logically lead up to the planning stage.

Selecting the Site. It may seem strange that in the development of the theme which I am discussing, treatment of the problems involved in selection of the site has been delayed until now and precedence has been given to determining the operating requirements and the character of the building. It is, however, of fundamental importance, in order to safeguard the success of the entire project, that selection of the site be deferred until definite conclusions, based on careful study and analysis, have been reached concerning the two important phases thus far presented. Not until agreement has been secured regarding these major aspects of the project should a commitment be made with respect to the site, and its acquisition should always be predicated upon its adaptability to the successful realization of the objectives of the institution.

It goes without saying that the financial burden involved in the acquisition of a site is of first moment. However, the tendency to regard this factor as controlling, without consideration of the many other angles of the problem, is extremely shortsighted. Basing a decision regarding selection of site solely on consideration of the amount of investment required, without taking adequately into account the bearing of the site on the type of building which may be erected and on the standards of economy and effectiveness which can be maintained from the operating point of view, has proved a very costly experiment to many institutions which have indulged in it. It cannot be stressed too often that the chief desideratum in planning of the character under discussion is the conservation of human energy and the attainment of lower operating costs. Since the value of money is a known factor and, except under abnormal conditions, does not fluctuate very widely, it may readily be determined how far a business organization is warranted in increasing its investment in the site in order to make possible the planning of a

building which, through proper design and effective arrangement of the interior, will have an increasingly favorable influence upon maintenance and operating costs.

Site Advertising Value. Of course, financial considerations are not the only ones extraneous to operating requirements which enter into the selection of the site. In some lines of business, notably in the case of banks, accessibility to customers is one of the chief elements to be taken into account. Then too, there is the factor of advertising value to be gained from prominence of location. While it cannot be gainsaid that due weight should be given to this element, in numerous instances its importance has been unduly stressed, with the result that wholly unsuitable sites have been purchased and operating activities, as well as costs, have suffered in consequence. When considering the feature of prominence, it should be recognized that, after all, this is mainly of local value and can hardly be expected to benefit materially a business of national scope.

As a case in point, the experience of a financial institution doing business in many states of the Union may be cited. Several years ago this organization, which is located in one of the largest cities of the country, erected a building for its own occupancy on a plot of ground facing upon a prominent avenue which was used as a main thoroughfare between the suburbs and the heart of the city and was traversed daily by thousands of automobiles. The executives of the organization deliberately chose the site because of its assumed advertising value and without regard to its adaptability to operating requirements. During the building stage, it was discovered that because of certain peculiar characteristics of the site only a building of unusual proportions could be erected thereon. The planning of the structure called for the solution of a number of very intricate problems, and the influence of the limitations inherent in the site was such that the cost per cubic foot rose to a point materially in excess of the cost generally incurred in the construction of comparable buildings. The executives of the organization were not disturbed, but consoled themselves with the belief that their new building in its prominent location would prove to be an asset of great value from the advertising point of view.

Several years have elapsed since this building was erected and, while it may be conceded that its location has afforded a stimulus to business activities in its neighborhood, the rate of progress of the organization itself has not been perceptibly accelerated. Indeed, it may reasonably be assumed that it would have prospered in exactly the same measure had it remained in its smaller home in a far less prominent location. Similar instances of questionable judgment can be cited.

Urban and Suburban Sites. Of general interest in connection with the selection of a site is the question whether it shall be located in the heart of the city or in a semi-suburban or suburban locality. This point should logically be settled by the nature of the business as well as by the operating requirements which must be met by the building to be erected. Generally speaking, banks must erect buildings in business districts; on the other hand, life insurance companies are not required to do so because their business is not conducted over the counter, so to speak. The latter observation holds true,

also, of many industrial organizations which find it convenient and altogether practical to erect office buildings in the vicinity of their factory establishments.

As far as operating requirements are concerned, banking institutions must of necessity subordinate these to the dominant characteristic of vertical expansion which is dictated by the location of their buildings on expensive ground in the heart of the city. To provide the space called for by the requirements of the ever-growing staffs of the larger banks, implies that quarters must be arranged on one or more floors above the main banking room. This condition at once introduces difficult problems of personal and mechanical intercommunication. With regard to life insurance companies, attention may be called to the fact that growth in such organizations lends itself most favorably to horizontal expansion. Because, as previously said, the nature of the life insurance business does not require that home offices should be located in the center of the city, it is in consonance with good planning to acquire a site in a semi-suburban location where land is comparatively cheap and horizontal expansion can be adequately provided at relatively low cost.

To sum up what has been said with respect to the problems involved in selecting the site, particular emphasis should be placed upon the necessity of deferring any commitments in this direction until reasonably exact knowledge has been gathered concerning the operating requirements of the organization and the type of building in which these may be most effectively brought to expression. Since the purchase of a site, generally speaking, constitutes a step which irretrievably commits the organization to a course of action, it is indubitably the better part of wisdom to study the problem in all its bearings before the decision is made to purchase a site. Beyond this, it is certainly of great importance to bring the architect and other consultants into the picture at the very inception of the building project so that their combined advice may be made available before, and not after, the organization has committed itself to so controlling a step as the selection of a site. Only in this manner may serious mistakes be avoided and the building program be based upon sound and constructive considerations.

General Planning of the Interior. We come now to a consideration of certain general problems which are associated with the planning of the interior of the building to be erected. Foremost among these is the manner in which the steel frame of the building is to be arranged. The standardized design of the steel frame of a commercial office building is too well known to require comment and, regardless of the extent to which steel columns present fixed interferences with effective office planning in such a building, little if anything can be done to change this condition.

With respect to the special purpose building, however, a good deal of latitude is permissible in arranging the steel frame so as to facilitate rather than obstruct the planning of an effective office layout. Successful office operation calls for the spacing of desks and the provision of aisles in harmony with definite standards sanctioned by experience. Where steel columns would interfere with the adoption of these standards, it is wise economy to increase the allowance for structural steel so as to make it possible to span greater distances than the usual twenty feet or thereabouts: it is not at all unusual

in special purpose office buildings to span distances of forty or even fifty feet without any intervening support. The benefit of such an arrangement lies in the fact that utmost flexibility of office layout can be achieved and every available square foot of space can be advantageously utilised.

In the early planning stages of a certain fourteen story office building in an eastern city, the commercial type of steel frame had been designed regardless of the fact that the building was planned for occupancy largely by one organisation with highly specialized operating requirements. Study of the plans by an engineer who was called in to analyze the office requirements, resulted in the conclusion to eliminate practically all of the steel columns which obstructed the usable space and to compensate for this elimination by increasing the carrying capacity of the columns in the walls of the building. The effect of this change was materially to increase the capacity of each of the floors for operating purposes and thus to make it possible to hold two entire floors in reserve for future development. If the original plans had been adhered to, it would have been impossible to provide any reserve space and in a short time the organization would have overflowed its housing facilities.

In planning the interior of a special purpose office building, problems of great importance arise in the location of the fixed service elements, such as elevators, stairways, toilet and locker rooms. Space will not permit of discussion of these problems in detail; therefore, I must content myself with emphasizing their general bearing upon good office practice. With due regard for city ordinances, stairways should be so placed as to avoid interference with office planning on the one hand and, on the other, to facilitate vertical communication from floor to floor. In buildings where horizontal expansion is the rule, stairways are usually placed at points equidistant from the extremes and this is also the case with elevators and toilet and locker rooms. With respect to the last two features, decentralization of these facilities is the modern practice, i.e., toilet and locker rooms for both sexes are provided on each floor of the building. In this way not only can the needs of office workers be adequately served, but the essential control, involving particularly the reduction of lost time to a minimum, can be maintained.

It is of course important to determine peak requirements when planning service elements and to realize that in a special purpose office building, as contrasted with the commercial type, arrival and departure of the entire building population occur within relatively short periods of time, at the opening and closing of the two work periods.

At this point I desire to interpolate the observation that wherever study of the traffic in a large office indicates that employees are constantly going to and fro, that fact is *prima facie* evidence of poor planning. In particular, it implies that departments have not been located in correct relation to one another or that service facilities have not been properly placed. Any evidence of constant circulation should be thoroughly investigated in order to determine what corrective measures can be applied.

Specific Elements of Layout. We come now to a consideration of specific elements of layout, such as wiring and equipment, which have a direct bearing upon clerical productivity. Despite the fact that there is an abundance of

evidence in support of the view that individual offices for small groups of clerical workers make it impossible to maintain proper standards of clerical effectiveness, the question of the open versus the private office is still debated on occasion. However, the open office principle is rapidly being applied in all modern buildings and it is justified by reason of the fact that it promotes the forward movement of work, permits of effective placing of movable equipment and files and of proper arrangement of desks, results in minimum circulation of employees, facilitates supervision, makes it possible to provide for proper entrance and egress and reduces the partition evil to a minimum. Indeed, the advantages to be gained through effective supervision over employees at work alone warrant arrangement of the space in line with the open office principle. There is a vast difference between apparent and real industry and the role of supervision in securing increasingly favorable results from a clerical staff is of first importance. Consequently, anything which can be done in planning an office layout to establish conditions conducive to the effective exercise of supervision will be reflected in the achievement of superior operating results.

With respect to wiring and equipment, it is essential to realize that we are living in an age of electricity and that much office work which was formerly performed by hand is now dispatched with the use of office machinery. In this connection we must consider not alone office operating devices but also intercommunicating systems of auditory, graphic and "carrier" types, time clocks, time stamps, protection systems and a host of other modern contrivances which are now commonplace in the well equipped business office.

Provision for the various types of equipment cited necessitates the introduction of a far more comprehensive scheme of ducts than is usual in the commercial type of office building. The modern practice is to install series of underfloor ducts for the accommodation of both high and low tension wires, so that by tapping the ducts at any desired location, current needed for the operation of machines may be secured at individual desks. The rate of increase in the use of electrically driven machinery in offices is so rapid that unless wiring requirements are amply supplied in the planning of a special purpose office building, it is not unlikely that the building will prove to be obsolete from the moment of occupancy. It is not overstating the case to assert that hardly any problem connected with the planning of a special purpose office building requires more careful and constructive study than that involved in the provision of effective and adequate wiring services, without undue cost.

There are numerous other problems connected with the planning of the interior which might be discussed, particularly if such service features as cafeteria, dining rooms, auditorium, medical department, etc., are to be incorporated in the building. The inclusion of services of this nature demands careful planning of their location, for not only must a suitable type of space and sufficient areas be provided, but the questions of convenience to operating departments and effect on use of stairways, elevators and other service facilities must be taken into account. Furthermore, special wiring and plumbing problems, as well as problems of illumination, ventilation and acoustics, are involved. In view of the fact that the provision of services

such as those described is somewhat unusual, except for very large organizations, I shall not devote more space to them except to say that there are material advantages in centralizing the activities in question and not permitting their location to interfere with the probable expansion of operating departments or with free intercommunication among such departments.

Record Vaults. Another specialized problem which should be mentioned is the provision of vaults. Facilities of this character are of course of prime importance for banks and other financial institutions and it is obvious that the highest type of protection must be installed wherever securities, especially of negotiable character, are to be stored on the premises. It is the inclination of business institutions occupying special purpose buildings to go to extremes, however, in their regard for the safety of their property and to seek to apply to office records and papers, a type of protection which is often as formidable as that deemed fitting for securities.

Slightly less cautious is the practice of housing records in so-called vaults which, in reality, are simple spaces surrounded by moderately fireproof partitions in which fire resistant steel doors have been inserted. Facilities of this character present two important problems: in cases where frequent consultation of the records enters into the daily routine, reference is hampered by reason of inaccessibility; moreover, the walls of the "vaults" often constitute fixed and formidable physical obstacles to proper space planning and location of equipment.

The modern practice limits to an absolute minimum the provision of vaults for the storage of records and, when these are of sufficient value to be provided with special fire protection, safeguards them through the medium of portable safe cabinets which are placed in immediate proximity to the desks of the employees who must consult their contents. Ideally speaking, office records should be retained in the working areas only as long as there is real need for consulting them regularly. When this period has passed, the records should be either destroyed or removed to storage warehouses, where space is much cheaper and where they may still be consulted on occasion, even though this involves a little extra effort.

If American business organizations could be persuaded to adopt a reasonable policy concerning the protection and preservation or destruction of office records, operating costs could be materially reduced, office layouts could be more effectively planned and most special purpose office buildings could be built on a smaller scale. Precautions must of course be taken from the legal point of view and the possible consequences of loss through inability to produce records needed in connection with lawsuits should not be overlooked; on the other hand cognizance should be taken of the statute of limitations. Much of the appalling amount of paper work performed in connection with modern American business procedure is a reflection of the inability of business executives to effect a sound compromise with an extreme standard of safety.

Physiological Factors. Intimately connected with the planning of the interior and of paramount importance by reason of their influence over operating results, are certain physiological factors which should be mentioned. I refer specifically to illumination, ventilation and noise reduction. It is on the correct solution of problems in these three fields that the physical

well being of employees, and therefore their productive capacity, must depend. To convey an appreciation of the importance of these three factors, let me state that in my judgment their combined influence over work results equals, if it does not exceed, the benefits which may be produced by a progressive program of personnel policies and practices, supported by an enlightened plan of financial incentives.

Illumination. There is a definite relation between standards of illumination and the quality and quantity of work produced by office employees. Because of the fact that many office buildings, including those of the special purpose type, are located on sites where adequate natural illumination cannot be secured by reason of surrounding buildings, the provision of artificial illumination to overcome this handicap assumes great importance.

The art of illumination has made rapid strides in recent years but many business organizations still fail to appreciate the necessity of maintaining liberal standards of artificial illumination so that the insidious effects of eyestrain may be eliminated or at least reduced to a minimum. It has long been established by illuminating engineers that a standard of eight to ten foot-candles of illumination at desk height is required for most types of clerical work. Inspection of many business offices, however, reveals the fact that this standard is infrequently adhered to and that false considerations of economy stand in the way of supplying artificial illumination of a character and intensity essential to both health and effective clerical performance.

As a rule it is difficult to trace the effect of a single physiological factor, but experience and study of illuminating problems justify expression of the opinion that it is apt to be an exceedingly costly matter to omit to provide a system of artificial illumination which is in harmony with the most approved modern standards. The reaction of employees to superior or inadequate illumination, either artificial or natural, is instant and direct. Because these considerations are valid and pertinent, it is essential that in the planning of special purpose office buildings the number, distribution and arrangement of ceiling outlets be carefully studied and determined in harmony with the requirements of the particular character of work to be undertaken. Moreover, careful consideration should be given to the type of fixture to be selected, and particular care should be taken to secure not only adequate intensity of illumination at desk height, but also uniform diffusion and freedom from marked shadows.

Although dependence for artificial illumination is placed chiefly upon fixtures suspended from the ceiling, certain other factors which are not always assessed at their proper value have a vital bearing upon the results to be accomplished. It is generally known, but not always observed in practice, that the color of the paint on the ceilings and side walls should be governed by illuminating requirements. The most satisfactory results as far as office workers are concerned, have been produced from a color scheme of flat white for the ceiling and light creamy yellow for the side walls. One has only to examine the ceilings and side walls of the average office building, however, to recognize that little, if any, attention is given to this important factor.

The last point I wish to make with respect to illumination is that natural, as well as artificial, illumination should be controlled. It is therefore of

importance to consider the manner in which windows may be most effectively screened so that the distribution of natural illumination will be uniform and free from glare.

Ventilation. Of even greater influence on the well-being and productivity of employes is the quality of ventilation. When considering problems of ventilation we are dealing with three elements, namely, temperature, humidity and movement of air. Although more or less effective standards with regard to these elements may be maintained by means of a heating system and the introduction of fresh air periodically through the opening of windows, conditions produced in this manner cannot be regarded as satisfactory in the long run. The opening of windows causes drafts and exposes the clerks near them to a range of temperature quite different from that experienced by those in remote portions of the office. Moreover, in cool climates during the winter months, it is seldom that windows can be opened for any length of time and, where dependence is placed upon them for ventilation, temperatures are usually found to be far too high and circulation of air inadequate.

The preceding considerations support the statement that an effective artificial ventilating system should be provided in special purpose office buildings. Such a system should be simple of operation and control, as well as based on sound physiological principles. Very satisfactory results have been achieved by a method which depends solely on the diffusion of fresh, unheated air which has been passed through a screen to remove its impurities. The air is drawn in from the most favorable outside point, cleansed, forced through ducts to suitably located openings at the ceiling and from these is sprayed across the room at relatively high speed. Thus, the air streams spread in fan shape along the ceiling and when the initial velocity has subsided, the fresh air drops gradually to the breathing zone and, mingling with the warmer air of the room, becomes palatable for human consumption. Under this method it is possible to bring about effective control of the temperature and to produce conditions which are satisfactory from the standpoints of humidity and circulation. Several complete changes of air are effected each hour, and the used air is forced out of the room through the gentle pressure which is constantly being exerted by the operation of the system.

The difference in work results produced by employes in well ventilated offices as contrasted with those possible of accomplishment in poorly ventilated offices, is startling to the investigator. With respect to the factor of temperature alone, it may be stated that on one occasion when the temperature in an office was deliberately permitted to rise to between 75° and 80°, a reduction in output of between 35 and 50 per cent was experienced. The cost of the investment in an artificial ventilating system is more than made up in a relatively brief period of time through the increased productivity of the workers exposed to this beneficial influence.

Noise Reduction. Finally, we have to consider briefly the subject of noise. Acoustical conditions are largely affected by three factors, namely, size, shape, and materials. It is the one defect worthy of note in connection with the planning of large open offices that operating conditions are not conducive to quiet. This is of course due mainly to the fact that so much office machin-

ery is constantly in operation and that the noise incident thereto is disseminated to all parts of the open area.

The statement is commonly made that individuals can adjust themselves to noisy conditions and that they do not mind them. In point of fact, they are obliged to use energy in combating such conditions and this energy is therefore lost as far as its effective use for working purposes is concerned. Although it is difficult to adduce scientific evidence in support of the detrimental effect of noise upon production, long experience and observation of scores of offices lead to the conclusion that the difference between noisy and reasonably quiet conditions may be expressed in terms of about 10 per cent of the total output. Even though this figure cannot be verified, it is substantial enough when translated into terms of clerical costs to more than support the investment required to correct noisy conditions by the installation of acoustical treatment.

Such treatment, if applied at the time when the building is in course of erection, might take the form of special acoustical plaster which is substituted for the finished coat on the ceiling. After the building has been constructed and occupied, recourse for office quieting purposes may be had to a variety of materials among which felt, suitably covered, is perhaps the one thus far most frequently used. Although the use of office quieting treatment is becoming more and more an integral part of building construction, the expense connected with its provision is still substantial enough to justify business organizations in deferring its introduction until occupancy of the new building for a period of time has demonstrated the extent to which it should be applied.

To sum up what has been said with respect to the so-called physiological factors, permit me to emphasize the belief that no matter how beautiful or costly a special purpose office building may be, it cannot be expected to be successful in the accomplishment of the objectives which it is designed to meet, unless adequate provision is made for effective illumination, ventilation and noise reduction. In view of the importance of controlling the physiological factors discussed, no budget covering expenditures for a special purpose office building should be approved unless it contains proper allowances for expenditures covering installations along the lines indicated.

Conclusion. In bringing this discussion to a close, let me state that presentation of the subject matter which it covers has been influenced by recognition of the fact that the standardized commercial office building adapts itself chiefly to the relatively simple requirements of many small tenants and that the larger the organization, the more specialized its needs become and the more difficult it is to meet them satisfactorily in such a building. In consequence, this discussion has centered largely around the special purpose type of building and I have endeavored, using my experience in the planning of both types of building, to justify the thesis that successful adjustment of building elements to specialized operating requirements has so beneficial a bearing on the productive capacity of the staff that savings in operating results often exceed the interest on the building investment.

As a supporting consideration, I desire to stress an intangible yet important factor which evidences itself in connection with special purpose office buildings. Management may be characterized as a dynamic force which tends to

influence the tempo of performance in harmony with the quality and effectiveness of the physical setting provided. In dealing with problems of office planning over a long period of years, I have become convinced that sound adjustment of physical environment and human beings to each other may be counted upon to reflect itself in an accelerating rate of accomplishment.

Let me finally state that a constructive and enduring solution of the problems of building economics can be achieved only by proper coordination of all elements which bear on the ultimate result. The client must know how to interpret his operating requirements and to measure the development of his organization so effectively that the architect may be furnished with a comprehensive program which covers all important business factors entering into the design and execution of the building. It is in assisting business organizations to formulate such programs that the management engineer has found in recent years a field of increasing usefulness. At all times recognizing the supreme importance of the function of architecture and the centralized responsibility of the architect, the management engineer collaborates with both the client and the architect in striving for the achievement of the ultimate desideratum of blending beauty with utility.

In the last analysis, the most searching test to which a special purpose office building may be put is the extent to which it retains its effectiveness with the passage of years and the changing operating requirements of the organization which it houses. A minimum of annual expenditure for physical changes should be required and the sums actually disbursed may be regarded as an index to the quality of the planning. Beyond this, if it is definitely established that year in and year out clerical operating costs show a definite downward trend, the ability and vision, technique and experience which entered into the original planning of the building must be credited with a large share in accomplishing such a result.

With the highest possible regard for the value of beauty of design and effective treatment of materials, it must be emphasized that the special purpose office building is but a means to an end and that the end is the attainment of enhanced operating results.

OFFICE FURNITURE

BY RITA H. HOPF, *Treasurer, H. A. Hopf and Company*

Just as the major physical characteristics of an office, such as layout, ventilation and illumination, have an important bearing on the health and production results of workers, so is there a close relation between the furnishing of the office and the welfare and productivity of employees. For this reason chiefly, but also for the sake of the appearance of the office and in order to control cost, the selection of office furniture is a matter which deserves careful study and consideration.

Broadly speaking, three classes of office furniture may be recognized: (1) executive furniture, (2) special purpose furniture, (2) clerical furniture. Of these, the last group, because of the number of persons affected and the more regular and constant use of furniture by them, is vastly the most

important; for the same reasons, this group lends itself more easily to general treatment. This article, therefore, will merely touch on the first two classes, so as to give as much space as possible to the discussion of clerical furniture.

Executive Furniture. Under this head is included all furniture to be used by the officers and directors of a company as well as by certain other important executives. It is often a moot point as to where to draw the line in supplying individuals with executive-type furniture but that is a matter of policy and organization, as well as of cost. Executive furniture should be used in the more important private offices, but not necessarily in all private offices; furthermore, executive furniture may often be used in open spaces, such as on the platform or main floor of a bank.

No principles can be laid down regarding executive furniture, as choice is governed largely by appearance which, in the last analysis, is a matter of individual taste. Some companies even go so far as to permit each executive to select his own furniture, with little or no guidance or control. This practice is not generally advisable, however, for it is difficult if not impossible under such conditions to convey an impression of unity and harmony. The best results will be secured if the purchase of executive furniture is entrusted to a central agency which will be governed by approved general standards in attempting to express the spirit of the organization in the selection of the furniture. It is desirable, however, that executives be permitted to have final approval of all furniture for their use.

Special Purpose Furniture. In many large offices, particularly in cases in which companies occupy their own buildings, space is set aside for such purposes as reception rooms, lunch rooms, rest and recreation rooms, auditoriums, libraries, medical departments, etc. The furniture to be used in these rooms is of such special character that it cannot be treated in this article but its purchase, also, should be entrusted to a central agency and governed by approved company standards, so that its quality and appearance may be in conformity with those of the general furnishing of the offices.

Clerical Furniture. As contrasted with executive and special furniture, the selection of which is controlled largely by its appearance, clerical furniture should be judged principally by its utilitarian qualities. This does not mean that the question of appearance should not be considered in the selection of clerical furniture any more than that the subject of utility should be neglected in the purchase of executive furniture. It implies, however, that clerical furniture should be regarded as an integral part of equipment for work and that the same study should be given to its suitability for this purpose as is given to the fitness of tools and machines. The large mass of clerical workers sit nearly all day at one type of work. The chairs on which they sit and the desks, tables, or files at which they work may help or hinder them in the performance of their tasks and may prove beneficial or injurious to their health, depending on their adaptation to the requirements of work and worker.

Need for Standardisation. It is well, therefore, to give sufficient study to the subject of clerical furniture so that correct solutions may be found to the problems involved and, once these have been reached, to establish

standards based thereon which will control the selection of all clerical furniture thereafter, subject of course to the findings of further investigation. There are many advantages to such standardization in addition to the fact that it ensures the use of the most fitting types of furniture for the purposes in question. In the first place it adds greatly to the appearance of the office to observe definite standards regarding materials, finish, height, and size. In the next place, it results in improved purchasing power. Moreover, it makes possible the interchange of pieces and permits of moving their location without disturbance to the layout. Furthermore, it simplifies the problem of replacement and minimizes delays in the delivery of orders.

The adoption of standard specifications governing office furniture does not necessarily imply that these should conform to the usual stock models. However, the number of furniture manufacturers is so large and the variety of stock carried is so great that it is usually possible to find any desired design stocked in some line. Whenever it is possible to purchase stock articles without sacrificing too much in fitness or utility, this should be done because specially designed or finished furniture is very costly and takes inordinately long to secure. Moreover, it is often very difficult to replace and, if the particular need should disappear or be modified, the furniture usually cannot be used for other purposes.

Material. Prior to about 1920 practically all office furniture was made of wood. Since then extensive use has been made of steel furniture and the trend in this direction appears to be increasing. Both materials are durable and practical and a sufficient number of stock styles and designs is available in each so that most clerical needs can be met. One of the principal advantages claimed for wood is that it is warmer in appearance and to the touch than metal; furthermore, wood is less subject to serious damage than steel. On the other hand, as steel furniture is made in standard sections, damaged parts may be readily removed and replaced.

From the point of view of fire hazard either material is satisfactory for general use in fireproof buildings.

A type of furniture which combines the principal advantages of both wood and steel is that made of a combination of both materials: steel frame and wood exterior. This combination, which is available in desks only, has much merit from the points of view of both utility and appearance.

Another material which should be mentioned is linoleum. This has found much favor as a top for clerical desks, particularly when made of steel. It helps to detract from the coldness of steel, affords an excellent writing surface and, at the same time, is easily cleaned and repaired. Although linoleum top desks are stocked in steel only, such tops can be added to wooden desks and this is a useful practice in restoring old and marred wooden furniture.

Finish. If wood is selected, there is a choice of three types of finish in stock furniture: oak, mahogany, and walnut. The last-named finish has only recently been made up in stock lines, however, and there is a more limited variety of types and makes from which selection may be made. Although mahogany and walnut are regarded as affording better appearance than oak, there are several advantages to oak furniture. It has a much lower light-absorption factor than either of the other finishes and therefore helps to

provide good illumination, particularly in large office areas. Furthermore, oak is considerably cheaper than the other finishes and can be more easily renovated.

In steel, up to the present time, olive green and mahogany have been the prevailing finishes; recently walnut has been added to these in most lines. All of these finishes have a high light-absorption factor. From the point of view of cost, the green finish is somewhat less expensive; there is usually no difference in cost between mahogany and walnut when both are stocked.

The major items of clerical furniture are listed below and will be treated in the same order:

- Desks.
- Tables.
- Chairs.
- Filing cabinets.
- Cupboards and storage cabinets.
- Safes and safe cabinets.
- Shelving.
- Lockers and coat racks.

In addition, reference will be made to the following general items of office furnishing:

- Floor covering.
- Window covering.

Desks. Three principal types of clerical desk are used in the office: (1) flat-top, (2) stenographic, (3) special purpose. The *flat-top desk*, which may be used for all general clerical purposes not involving the use of machines, is available in single or double pedestal styles or may be had in the so-called "corporation" type, which has only one or two small drawers on each side and may or may not include a center drawer.

As a rule, the mistake is made in offices of supplying desks which are too large for the needs involved. This not only adds to initial expense but is wasteful of floor space and often results in unduly crowding the office. The following flat-top desk sizes are suggested as economical and satisfactory for the uses described.

Use	Type and Size
For work not requiring the use of large-sized records or many papers at a time (often used for salesmen or investigators).	Single pedestal, 43 or 45 inches.
For work requiring the use, but not storage, of many papers.	Double pedestal, corporation type, 50 inches.
For work requiring the use of many papers and storage space.	Double pedestal, 50 or 55 inches.
For supervisors or for clerks using large records, binders, etc.	Double pedestal, 55 or 60 inches.

There is a tendency in the direction of decreasing the number of legs on standard, double-pedestal type desks by omitting the four center legs. This tendency, which was begun in wooden desks, has been developed chiefly in steel desks. It has the advantages of giving free leg room and of permitting better cleaning under the desk. Four-legged desks are available in the stenographic types described below as well as in the flat-top desk.

The *stenographic desk* may be had in three principal types (1) drop head, (2) solid top, (3) secretarial. The second of these types is not usually catalogued but may be secured in large quantities from manufacturers at reasonable cost. It may be made either in a low style with a continuous flat top, or in desk height with a sunken bed for the machine. The usual uses for the various types are indicated below:

Use	Type and Size
For continuous typing or stenographic work.	Single pedestal, drop head 43 or 45 inches, or solid top 50 inches.
For typing or stenographic work involving some clerical work.	Double-pedestal, drop head 50 or 55 inches.
For secretarial work or clerical work involving use of typewriter.	Double-pedestal, secretarial (machine in pedestal) 60 inches.

For clerical work entailing the use of certain types of machines or records, *special-purpose desks* must be supplied. Desks of this type may be had in stock designs for such purposes as the following: machine billing and book-keeping, comptometer and calculating machine operation, key punching, storage of card or ledger records, etc. As far as desks to house special machines are concerned, there is little latitude in choice of style or size but, whenever possible, it is well to adhere to the standard sizes provided for other clerical desks.

The storage of card or ledger records in desks is desirable in cases in which the records are handled almost exclusively by the clerk who does the posting. Wherever reference to such records must be made frequently by others, it is preferable to house the records in files and to supply an ordinary desk or table for the posting clerk. Special desks for the storage of cards or records may be had in tub or drawer type. Tub type desks are available for seated or standing posture and may be had either with fixed or with movable writing surface.

Tables are employed for a number of purposes in the office and their use is to some extent infringing upon that of desks. The chief uses of tables are enumerated below:

1. In place of desks for clerical operations requiring no drawer space.
2. For general utility and to serve as bases for visible indexes and machines not otherwise housed.
3. To supplement the desks of executives and department heads.

Wherever tables are used, their dimensions should conform to the standards established for desks. This will permit of interchangeability, improve appearance, and facilitate layout.

Chairs. One of the most important pieces of furniture in an office is the chair. On it, largely, is dependent the comfort and health of the clerical worker and therefore the effectiveness of his work. Great care should therefore be exercised in the selection of chairs for clerical employees. This is particularly so in the case of workers who are confined to their desks most of the time. The main features to which attention should be given are the following:

Revolving Type. For all kinds of clerical and stenographic work a chair of revolving type should be used.

Height. Chairs should always be adjustable as to height so that the occupant may maintain a comfortable working position.

Back. The back should also be adjustable so as to afford support and permit of relaxation.

Seat. The seat should be sufficiently large and should be scooped out so as to conform to the body.

Arms. Chairs should not be equipped with arms, except for the use of executives.

Casters. The use of a ball-bearing, swivel caster made of a material other than wood or metal adds greatly to the utility and comfort of a chair and saves wear and tear on the floor covering.

In addition to chairs for the use of clerical workers, two kinds of chairs are ordinarily used. The executive chair is of the revolving type, is equipped with arms and is supplied with either a perforated or upholstered leather seat and upholstered back. The side chair, for the use of visitors, may be of any straight type.

Filing Cabinets. The principal types of filing cabinets are (1) vertical, (2) horizontal, (3) counter-height, and (4) safe files. These may be had to house materials of various sizes, and great flexibility can be secured in building them up provided uniform standards are maintained.

Where the question of filing capacity is dominant, *vertical files* should be used. Where this is complicated by the factor of serving the public or by the requirement of a working surface, *counter-height units* are indicated. The use of such units often makes it unnecessary to build special counters of wood or other material, which have no utility aside from their use as counters and can seldom be reused when a change in layout is made. *Horizontal units* are practical where materials of various dimensions have to be housed in one stack; their use is usually reserved for executive offices. *Safe-files*, which are constructed to provide greater fire resistance than is afforded by the ordinary filing cabinets, are made in letter and legal-sized vertical units. They supply a need halfway between the filing cabinet and the vault for the filing of important documents which have to be specially protected against the fire hazard.

Cupboards and Storage Cabinets. Unless used in supply or record storage rooms, these should be of counter- or vertical-file height and should conform in material and finish to the standards established for filing units; otherwise they become unsightly. Their chief use in the office is to maintain the limited amount of supplies which must be kept on hand in the operating departments and to store books or valuable small machines overnight. Cupboards

may be supplied with hinged or curtain-type doors or may be had without doors.

Safes and Safe Cabinets. For the storage of valuable materials which must be protected against both fire and theft and at the same time must be readily available for use, safes or safe cabinets may be used. Both of these types of equipment can be secured in counter-height and can thus be joined with batteries of files to make a continuous counter. The use of safes and safe cabinets as a substitute for vault storage provides flexibility in layout and convenience in use.

Shelving. Great economy and flexibility can be secured in the storage of supplies and other materials through the use of sectional steel shelving. This may be built into stacks of any desired height, width, and depth, but a depth of twenty-four inches has been found to be the most practical. It is sometimes desirable, however, to use deeper units at the base, extending upward to approximately counter height, so that the upper surface of these units may be used as a working counter for clerical operations or wrapping. Sections of steel shelving may be transformed into cupboards by the application of hinged doors. Shelving may also be used to serve as book stacks.

Lockers. Where space permits it is desirable to furnish employes with individual lockers for their wraps. Such lockers are made of steel and may be had in one-, two-, seven-, and eight-compartment types. A depth of from fifteen to twenty-one inches is satisfactory; width and height vary according to the number of compartments. Single- and two-compartment lockers are usually built in batteries; therefore, in the purchase of this type of equipment, care should be taken to restrict the overall width of any battery to 54 inches or less, so as to insure easy handling and flexibility of arrangement. The provision of sloping tops for lockers is advantageous from the sanitary point of view and also because it prevents the placing of packages and newspapers on top of the equipment.

Where it is not feasible to supply individual lockers, coat racks with hangers and hat shelves may be provided.

Floor Covering. The usual cement floors of offices require a special floor covering to adapt them to daily work. The following tabulation indicates suitable types of floor covering for the various areas mentioned

Area	Material
Reception space.	Rubber, linoleum or mastic tile; carpet.
Interior corridors.	Linoleum; linoleum or rubber tile; mastic or mastic tile.
Clerical offices.	Same as corridors.
Executive offices.	Rugs over wood, cork or linoleum; cork; carpet.

Window Covering. Better control of daylight illumination can be obtained by the use of a special type of blind than by that of the ordinary window shade.

The Venetian blind, a type in which the light is transmitted through the spaces between adjustable wooden slats, makes it possible to secure sufficient illumination and ventilation even when the blind is completely drawn. The slats may be deflected upward or downward to control glare.

Another type of blind which has proved satisfactory is one which is made of accordion-pleated fabric and is controlled by cords which make it possible either to raise the blind from the bottom or to lower it from the top to any desired position. In this way light is permitted to enter from either the top or the bottom of the window, depending on the angle of the sun rays.

The use of draperies at windows is suitable only in executive offices and special areas such as reception rooms, lounges and dining rooms.

In concluding this article, a word of general guidance regarding the selection of office furniture should be given. Although the question of economy will always exercise a controlling influence on this subject, within the limits set by this consideration, four major elements should be kept constantly in mind: *adaptability, simplicity, durability, and good taste*. If these characteristics are present, and *uniform standards* are observed, the furnishing of the office cannot fail to be an asset in improving clerical performance and in making the working areas attractive to those who spend their days in them, as well as to outsiders who have business with the organization.

OFFICE MACHINES AND APPLIANCES¹

BY J. H. MACDONALD, *Auditor and Office Manager, Keller Mechanical Engineering Corporation*

Scope of the Discussion. Before proceeding to a specific discussion of the various machines available, what they are, what they do and how they do it, the basis upon which this material has been prepared should be made clear. First, instead of citing numerous applications of various machines to specific cases, the discussion has been confined largely to statements regarding the machines themselves, what they will do, and how they do it. This has been done because it has been the writer's experience, that while rather dramatic accounts of machine installation may make very interesting reading such discussions are not especially helpful in working out one's own particular problem. In other words, it is much more important that one know that there is a machine made especially to perform a certain task than it is to be told that a certain public utility company, manufacturing company, retail store, or bank now has only eleven clerks doing a particular job with the aid of machines which formerly necessitated the employment of eighteen. Second, for obvious reasons manufacturers' names have been omitted throughout. Third, no attempt has been made to describe in minute detail the purely mechanical operation and parts of the various machines. Fourth, while an attempt has been made to secure information from all

¹ Certain sections of this paper are summarized by permission of the publishers from *The Office Appliance Manual*, ed. by W. H. Leffingwell

manufacturers regarding their equipment, no one is infallible and it therefore may be that certain devices with which some readers are familiar are not mentioned. Last, the whole point of view has been to attempt, not the preparation of the encyclopedia of office appliances, but rather a survey of what the field offers. For this purpose the following classification has been used:

1. Calculating machines.
2. Billing machines.
3. Bookkeeping machines.
4. Electric accounting and tabulating machines.
5. Cash registers and coin handling machines.
6. Dictating machines.
7. Typewriters.
8. Duplicating machines.
9. Addressing machines.
10. Time-recording machines.
11. All others.

Calculating Machines. In this group are included only those machines whose sole work is calculating of one sort or another. Machines in which calculation is a subsidiary function of the principle operation, such as billing and bookkeeping machines, for example, which automatically add, subtract, extend invoices, figure discounts, etc., are included in the latter group.

Adding Machines. The simplest and best known type of calculating machine is the adding machine. While subtraction, division, and multiplication can also be done on certain types of so-called adding machines, by the use of reciprocal numbers, etc., it is assumed that operations requiring only addition are to be performed. Adding machines may be classified as follows:

1. Non-listing type.
2. Listing type.
3. Full or standard keyboard type.
4. Ten-key type.
5. Hand-lever type.
6. Automatic electric type.

A number of machines now on the market offer combinations of the above types which will be described presently.

Non-list Type. This is the simplest type of straight adding machine. Each digit is represented by a separate column. Models containing from seven to seventeen columns may be secured. As each key is depressed, counters in the machine are turned as the lever is pulled down, in the case of the hand-lever type, or are actuated by electric contact, in the case of the automatic electric type. The total accumulates at either the top or bottom of the machine in the space provided. To clear the machine it is usually necessary simply to depress the total key which automatically returns all figures in the total column to zero.

Advocates of the non-list type of adding machine claim that an experienced operator can add a column of figures twice as fast as one person alone can both operate the machine and then check back the figures appearing on the

listing tape against the original source. On the other hand in many cases it is desired to file the adding machine tape as a permanent record with papers to which it relates.

Listing Type. The principle of operation and use is the same in this type as in the non-list type except that each number is written on a tape together with totals.

Full or Standard Keyboard. Every adding machine is of either the full-keyboard or ten-keyboard type. The full-keyboard type contains as many rows of keys, each from one to nine inclusive, as the digit capacity of the machine. The chief advantage of this type is simplicity of operation and understanding. This type is most frequently found in smaller offices where a number of people have occasion to use an adding machine, but where there is no high degree of specialization.

Ten-key Type. In the ten-key type each key represents a digit, but the mechanism automatically takes care of the numerical or columnar order. While there are a number of straight adding machines of this type on the market, the most frequent use of the ten-key mechanical principle is in combination with other appliances such as the billing machine, bookkeeping machine, etc.

Hand-lever and Automatic Electric Types. Every adding machine is either of the hand-lever or automatic electric type. In the hand-lever type the lever is pulled down each time after the number is set up in the machine, while in the automatic electric type the slight touch of a bar actuates the mechanism. Obviously the electric type requires less manual effort and less time and it is therefore to be expected that this type is most frequently used where a large volume of work and a high degree of specialization result in the continual use of the machine by a single operator or a group of operators. In the smaller office the hand-lever type is much more frequently to be found.

Combinations of Various Types. For the sake of simplicity and clarity each type has been discussed separately. It should be emphasized however, that every machine represents a combination of two or more of the types mentioned. Thus we find the list machine in either the hand-lever or the automatic electric type, the full-keyboard or ten-key machine in either the list or non-list type and with either hand-lever or electric motivation. The kind of work to be done, the volume of it, the degree of specialization, and the cost are the controlling factors in deciding which type and manufacturer's make is best suited to a particular kind of work. Adding machines are one class of office equipment in which standardization on one manufacturer's make throughout the entire organization is not necessarily the best practice, in fact, in many large companies one finds a number of makes of adding machines, each chosen because of its adaptability to the particular work of the department in question.

Other Calculations. As previously mentioned, so-called adding machines may be and are widely used to perform many calculations other than straight addition. By the use of reciprocal numbers, etc., subtraction, multiplication, and division may be performed with as much ease, although not necessarily as quickly, as addition. Therefore, in considering the purchase of a calculating machine which is built for the specific purpose of sub-

traction, division, and multiplication, as well as adding, one should carefully consider the number of such calculations to be made, the relative time required to make them compared to the time required if a straight adding machine is used, etc. To buy a direct subtraction machine or one which will multiply and divide automatically, simple because there are such operations to be performed in the office may be unwise, unnecessary, and expensive.

Characteristics. Three points characterize the calculating machine field, so far as operation is concerned. First, machines are of either the direct key-driven or lever-operated type. In the direct key-driven type the value of the keys is added as the keys are depressed, and the total appears on the dials. In the lever type (either hand or electric operated) the lever must be moved after the keys are depressed. Second, calculating machines are the full-key rather than the ten-key type. Third, and this is a difference sometimes forgotten, the calculating machine is a non-list machine. When used in combination with other operations such as the extension of an invoice in the case of a billing machine, for example, the printing of the amount of the charge may be said to correspond to the listing function. The machine which does only calculation, however, is the non-list type.

Uses. The field of calculating machines is so broad and well known that there is no need to cite examples here. Wherever the volume of work and the degree of specialization warrants their use, calculating machines perform an indispensable service. Railroads, banks, public utilities, stores, manufacturing plants find innumerable uses for such machines in their billing, bookkeeping, cost accounting, engineering and sales departments. However, in the last four or five years there has been an increasing tendency to combine the calculating machine function with others, such as bookkeeping, general accounting, cost accounting, analytical work, etc., in which the results of the calculation appear in written form on a permanent record, such as a bill, journal, a customer's account, a sales analysis sheet, a cost sheet, etc. Consequently, while it would not be true to say that the field and use of calculating machines is decreasing, it is most important to bear in mind, if one is considering the purchase of such a machine, that such combinations as have just been suggested apparently represent the trend in this field. With the tendency very distinctly towards the greater use of machinery in office work it is not unnatural to find such combinations developing and to expect that they will continue to develop to a still greater degree as time goes on.

Billing Machines. The modern billing machine is a combination type-writer and calculating machine. It is possible, through the proper collation of forms, to make additional copies for other purposes such as packing slip, shipping copy, manufacturing department copy, express receipt, etc. Furthermore, sales distribution by various classifications, account analysis and other distribution or analytical work can be performed at one writing in many cases.

Types of Billing Machines Available. Billing machines may be classified as follows:

Cylinder type, in which the forms are fed around a cylinder in the same way that a letterhead, carbon paper, and second sheet are inserted and turned in an ordinary typewriter.

Flat-bed type, in which the forms are contained in a bed over which the writing unit moves.

Machines which do not compute but merely type.

Machines which type, add, and subtract.

Machines which type, add, subtract, multiply, and divide.

Machines which use cut forms.

Machines which use continuous-length forms.

As in the case of the classifications used for adding machines, each machine is really a combination of two or more of these various types such as flat-bed machines which type, do all calculations, and use continuous length forms, cylinder-type machines which add and subtract only in addition to typing, and use cut forms, etc. Obviously the cylinder type which merely writes and does no calculation of any sort and uses only cut forms is fundamentally nothing more than a typewriter with the stops adjusted to correspond to the width of the various columns on the form. On the other hand the type which writes, does all four kinds of calculations, and can be arranged for writing many forms at one time, including analytical and classification work, is a machine capable of combining many operations in one, whether these were formerly performed by hand or by other machines. Such types of billing machines are available in both the cylinder and flat-bed styles.

Advantages of Using Billing Machines. The advantages of using billing machines are numerous, particularly those types which combine typewriting with at least addition and subtraction, if not multiplication and division. In the first place the machine is both a typewriter and calculating machine, as it is possible to use each mechanism separately. Second, by the proper collation of forms as high as eighteen copies may be made at one writing, thus saving much subsequent rewriting and copying which it is necessary to do if hand methods or typewriters are used for preparing bills. Third, calculations are known to be correct because they are mechanically performed. Billing machines have automatic devices which lock the machine when an error in posting has been made. Fourth, various distributions may be made at the same time that the bill is being written by means of totalisers or registers which accumulate vertical totals by columns in addition to the cross computers.

Department stores, public utilities, manufacturing companies, both large and small, wholesale concerns, and railroads use billing machines to great advantages. Instead of the old method, under which everybody who could operate a typewriter "got on the bills" at the end of the month, and subsequent entries to other accounts and statistical records were long delayed, the billing machine not only keeps the billing work currently up to date, but writes many other records at the same time with greater speed and accuracy.

Bookkeeping Machines. In discussing bookkeeping machines, care must be taken to distinguish between those machines in which the fundamental characteristic is the use of ledger sheets of various kinds and what some manufacturers have termed "electric accounting," or machines in which punch cards take the place of ledger sheets. For the purpose of this discussion, we shall refer, under the classification of bookkeeping machines, to

those machines in which a ledger card or sheet of some kind is used, leaving for the following section, Electric Accounting and Tabulating Machines, those machines which use punch cards as a basis.

Fundamental Characteristics and Principles of Operation of Bookkeeping Machines. Bookkeeping machines are not unlike billing machines in that fundamentally, with the exception of the bookkeeping machine of cash register origin, they represent a combination of typewriter and calculating machine. In fact, a number of manufacturers who advertise machines for billing work and also bookkeeping machines, really make but one machine which can be used with slight variation in detail for both billing and bookkeeping work. Again, as previously explained in connection with billing machines, the fundamental principle of operation is the writing of a number of records or forms at once, thus eliminating the copying necessary with hand work and through mechanical calculation and devices which lock the machine when an error has been made, insuring accuracy of posting.

Variety of Uses Obtainable. Among the records for which bookkeeping machines may be used are the following:

Purchase journal.	Accounts payable ledger.
Distribution journal.	Remittance advice.
Sales journal.	Proof journal.
Cost of sales journal.	Cost sheets.
Cash received journal.	Stores records.
General journal.	Inventory records.
Accounts receivable journal.	Payroll records.
Customers statements.	

In using the machine for accounts receivable work for example, the accounts receivable ledger is posted, the customer's statement prepared and a proof journal made all at the same time. The proof journal, obtained as a by-product of the posting of all accounts, provides a complete permanent record and proof of all items posted. Charges, credits, and balances are automatically accumulated for proof, and the totals are printed in the proper columns on the proof journal. Credit balances are automatically printed in red figures on original forms and also marked with a symbol "CR" which shows on all copies.

Purchase and payment records are handled in the same manner as accounts receivable. If an accounts payable ledger is maintained (providing a permanent record of purchases against which vendors' statements may be checked to prevent duplication of payments), a remittance advice may be prepared as each accounts payable ledger account is posted. Transactions and journal totals which affect the asset, liability, revenue and expense accounts in the general ledger may be posted daily, if desired. Thus financial statements may be compiled quickly and accurately, because all accounts will be posted and proved to date. In the case of stock records where it is desired to keep a record of both quantities and values both by units and totals, bookkeeping machines will be found extremely useful. The machine extends a new balance of both quantity and value with each posting, affording a perpetual inventory.

The machine automatically accumulates the total quantity and total value of all items posted, which provides proof that all items have been posted, and none posted twice.

Multiplying the quantity balance by the average price on the ledger proves (1) the pricing and figuring of the requisitions or other posting media, (2) that postings were made to the right account, and (3) that all new balances are correct. Proving is facilitated by using the proof journal because the postings on the journal can be verified while other postings are being made. However, the proof journal can be eliminated, if desired, by offsetting the affected ledger sheets when posting so that the proof calculation can be made directly from the account.

Bookkeeping Machines of Cash Register Origin. The bookkeeping machine of cash register origin differs from other bookkeeping machines both in appearance and operation. Instead of the usual typewriter cylinder or flat-bed type with the writing unit above, this machine consists of a bank of keys very similar in appearance to a cash register. One set of keys is for debits, another for credits, the rest for balance, total, subtotal, error, etc. In place of the cash drawer, however, there are two horizontal writing surfaces, one having place for the insertion of a card or cards for posting and the other containing a continuous roll or audit sheet on which are automatically posted all entries made by the machine.

In using the machine for accounts receivable work for example, the old balance as shown on the customer's ledger card is picked up as is the case with other bookkeeping machines. Both card and statement are then inserted in the machine, the amount to be posted is set up by depressing the proper keys and the machine operated. As the figures are printed on the ledger card and statement, they are also printed on the audit sheet, thus giving an itemized journal or record of all transactions passing through the machine. The balance is then secured by depressing the balance key, which automatically adds or subtracts from the previous balance. The new balance is then printed on the ledger card and customer's statement.

Where installment sales and payments are handled, this machine is particularly useful, especially if the customer has a payment book of some sort which he keeps, as is usually the case. In this case the ledger card and the book are inserted in the machine together, the amount of payment recorded, the book returned to the customer and the ledger account to the file. Savings banks, building loan associations, hotels, personal loan companies, retail stores, and many other lines of business in which installment payments may be made either by check, by mail, or in cash by the customer personally, have found this machine particularly useful.

Advantages of Bookkeeping Machines. In addition to the usual advantages secured by the use of proper office machinery, bookkeeping machines have made one outstanding contribution to modern accounting and office management, namely, the virtual elimination of tedious hours of overtime at the end of the month and year on the part of bookkeepers and clerks. Bookkeeping machines make it possible to keep all accounts posted up to date and constantly in balance which in turn enables the preparation of statements whenever they are needed. This kind of day to day control alone, to say

nothing of greater accuracy, speed and better appearance, more than justifies the increasingly wide use being made of bookkeeping machines.

Electric Accounting and Tabulating Machines. During the past five years an increasingly large number of business organizations have come to realize the fact that management and control are based first of all on facts. Subdivision of accounts, detailed analysis of sales and manufacturing expenses, break down of items formerly carried as one lump-sum total are just one or two of the many things being done along these lines. To get the facts easily, promptly, and economically, however, necessitates the use of machines. The manufacturers of tabulating equipment have not been slow to recognize these new demands and to prepare themselves for them.

Tabulating equipment is of two distinct types. First and perhaps best known is that which uses so-called punch cards or tabulating cards as a basis. Second, there is a machine again of cash register origin as in the case of the bookkeeping machine just described, in which banks of keys similar in appearance to cash registers are depressed and printed results secured.

Uses of the Equipment. Both types of equipment are used for two distinct purposes, namely, outright statistical and analytical work as well as general and cost-accounting work. Analysis and classifications of sales by salesmen, by price lines, by territories, by classes of product, by profit lines, by kind of business sold constitute some of the uses to which such equipment is being put in the sales field. Large department stores use such equipment extensively for such things as inventory analysis and classification, charge account analysis showing the number of charge customers who bought in five departments only, six to ten departments, eleven to fifteen departments, etc., what they spent per month or six months, etc. Life insurance companies have a wide variety of uses for such equipment for purely statistical purposes.

More recently, however, considerable use of tabulating equipment has been made in the field of general and cost accounting. In many companies, for example, a set of tabulating cards comprises the accounts receivable ledger. A card is kept for each customer showing the sales order number, invoice number, date of sale, kind of product sold, amount of the sale, date paid, discount taken if any, open balance, etc. Accounts payable records are kept in the same way. Stock records, payrolls, general expense accounts are similarly handled. In the field of cost accounting, tabulating cards showing the amount and value of direct labor and direct material used on each job or lot, as well as the burden applicable to the job, the total amount of manufacturing cost, etc., have replaced cost sheets or have at least supplied the details. Labor and material tickets may be similarly handled. It is because of this more recent development in the use of tabulating equipment wherein manufacturer and user alike have gone far beyond the original idea of using such equipment for statistical and analytical work only, that electrical accounting and tabulating are discussed together.

Fundamental Principles of Operation of Tabulating Equipments Which Use Punch Cards. Tabulating equipment using punch cards consists in every case of three separate machines, namely, the key punch either electrically or hand operated which punches the holes in the tabulating cards, the sorter which sorts the cards passed through it into various groups depending upon

the position of the holes punched in the cards, and the tabulator which calculates and which in some cases records and prints the results.

The principle of the tabulating or punch card is simple. The card itself is divided into various so-called fields in each of which there are vertical columns of figures numbered from zero to nine. The figures applicable to each field are recorded by punching out holes in the appropriate columns. For example, in the case of stock records, the quantity received, the quantity issued, the balance on hand, together with the values and dates in each case, the invoice number on which the material was purchased, the date the order was placed, production or sales order number or material requisition number are indicated by punches in the proper holes. One of the latest developments is an arrangement whereby the key punch may be connected with a standard typewriter or posting machine so that a bill or other typewritten record may be made at the same time that the card is being punched.

The purpose of the sorter is automatically to select or sort all cards in which a particular hole number has been punched. Only one column can be sorted at a time. The cards are passed through the machine and those having holes punched in the column for which the selector or pointer has been set are automatically dropped into the containers or trays provided, the balance of the cards accumulating at one end of the machine. The trays are either vertical or horizontal. While it is frequently necessary to pass the same cards through the machine several times in order to secure the desired arrangement due to the fact that the machine will select only one column at a time, this is not a serious drawback as the machine can sort at the rate of 400 cards per minute.

After the cards are sorted as desired, they are passed through the tabulating machine and subtotals and totals secured either from counters or printed direct.

Advantages and Disadvantages. The outstanding advantage of the tabulating card system is that information can be analyzed and rearranged in numberless different ways automatically and speedily without the necessity of rewriting, rearranging, and reclassifying. Economy of space is also an important item. For a business which has enough transactions or postings to keep the equipment reasonably busy, information of many kinds, or the same information classified, in many ways, can be secured most easily and economically. On the other hand it unfortunately appears to be true that in some cases, at least, an installation of such equipment should never have been made, due to the fact that the various analyses made from the cards are never made use of by the executives in any more than a superficial way at best. The fact that one can secure all manner of classifications from a single card seems to have an appeal to many executives who do not stop to think, when considering the purchase of the equipment, just how much use they are actually going to make of the information after it has been presented to them. One manufacturer's representative with whom the writer talked told of an installation he had recently made in which he had frankly said to the prospect that he did not advise the use of the equipment because he could not see that the results could be made sufficient use of to justify the cost. The reply was "That's all right, my friend Mr. Jones has one of these

machines in his office and I don't want him to think that I am less progressive than he is."

It should also be remembered that with the exception of the largest and most expensive types of tabulating equipment, no written record other than that indicated by the holes in the cards themselves is made and that all the calculations to secure figures to be punched out on the cards must be made on other machines. This latter point is mentioned merely to contrast its operation and results with certain kinds of bookkeeping machines which both write and calculate.

Tabulating Machines of Cash Register Origin. These machines, sometimes called machines of the ticket-producing type, have a keyboard very similar in appearance to a large cash register, as already explained in connection with their use as bookkeeping machines. In fact, by locking one key the accounting or posting machine can also be used as an analysis machine if no more than eighteen classifications or totals are needed. However, due to the fact that they are not descriptive writing units, as is the usual bookkeeping machine, but are equipped with a number printer which prints descriptive numbers or symbols which may be used to identify each transaction, their widest use has been as analysis machines.

A total of twenty-seven different classifications can be secured, each with subtotal and grand total. The large number of totals with which these machines are provided eliminates the necessity of hand sorting of the records from which the information is taken. The machine is electrically driven, no manual work other than that of depressing the keys being necessary. At the base of the keyboard an audit-sheet continuous-roll form is provided. This contains a detailed record of each transaction enabling the operator to verify at sight the correctness of the previous thirty-four transactions. A series number is also automatically printed on this audit sheet, so that any item may be traced and the total number of transactions handled easily ascertained.

Machines of this type have found wide use where the total number of classifications needed in any one analysis does not exceed twenty-seven. Study of a particular situation frequently shows that while a considerably larger number of classifications may be at first thought necessary, a large per cent of the total items to be handled are in very few groups, often much less than twenty-seven in number.

The obvious advantage of this type of machine as contrasted with tabulating card equipment for analysis work is that only one operator and one machine are necessary, compared with three machines. On the other hand, tabulating equipment of this kind is not as flexible and furnishes no permanent record of the operation comparable with the completed punched tabulating card, other than that made on the continuous-roll audit sheet.

Cash Register and Coin-handling Devices. Cash registers are made in both print and non-print models and are either key set or lever set in mechanical operation. The printer type may be secured in any one of four models.

1. *Total Printer.* This type provides a total record which may be printed at any time upon a slip of paper. In addition to the total of sales, there are

printed on the slip the date, the number of transactions, the number of times the "no-sale" key was used, the number of times the adding and counting mechanism was reset to zero, and the number of the machine. At the end of the day the printed slip may be filed as a permanent record of the day's business.

2. *Detail Printer.* The detail strip shows the amount of sale of each item, the nature of the transaction, and the salesperson's initial or department symbol. The register of this kind is equipped with one or two total-adding counters which print the total of the accumulated amount.

3. *Detail and Receipt Printer.* The detail and receipt printer is composed of the same characteristics and features as the detail printer but has in addition the receipt-printing device which issues a ticket or receipt to the customer. The receipt bears the total of the sale, transaction number, and date of sale. The detail and receipt-printing type of cash register is operated by motor or hand power after the amount keys are depressed.

4. *Detail-total Printer.* The register of this kind prints and adds the items of sale, then prints and records the total. This register retains a detailed record and issues a receipt giving the itemized sales and the total.

Coin-handling Machines. Coin-handling machines may be discussed under two heads, namely, coin-changing devices and machines especially built to handle change in bulk.

Coin-changing Devices. The coin-changing machine consists of three essential parts, the coin tray or the slots at the top of the machine in which the various denominations of change are kept, the keyboard consisting of keys, one row for each unit, which when depressed release the desired number of coins, and the coin chute or the channel through which the coins fall. The type of keyboard is the distinguishing characteristic of the two types of machines available. In one type the machine delivers the amount indicated by the key depressed, i.e., 17, 42, 59 cents, etc., while in the changer type the machine computes and delivers the difference between the amount shown on the key which is depressed and \$1.00. The 17 cents key in this case delivers not 17 cents but 83 cents.

Coin-handling Devices. Coin-handling devices are of three kinds, namely, coin separators, or machines which simply sort mixed change, coin-counting and packing machines, which count and wrap coins from 1 to 50 cents, one denomination at a time, and coin separators and counters which separate, count, and wrap all in one operation. Tokens may also be handled in the same way. Many separators utilize centrifugal force by throwing the coins from a revolving disc into various-sized slots as the disc turns. Others work on what is essentially the sieve principle. Machines are either hand or electrically driven. Some machines pack the counted coins in paper wrappers or tubes, others load it in bags.

Dictating Machines. The dictating-machine system, by means of which the voice is recorded on a wax cylinder and later transmitted back to the typist, consists of three separate machines, namely, the dictator or dictating machine, the transcriber, and the shaver. The dictator or correspondent uses only the dictating machine, the typists use only the transcriber, while the office boy is usually king in his own right of the shaver.

The Dictating Machine. By means of the dictating machine the voice is recorded on a wax cylinder placed upon a flexible mandrel, or cylindrical spindle, which is rotated by a small electric motor. The vibrations of the dictator's voice are recorded on the cylinder by the process of engraving on the wax surface.

The machine is small and occupies little space, so that it may be placed on the dictator's desk or on a stand at the side of his desk. If the dictator is interrupted, or if for other reasons he wishes to have repeated what he has just dictated, he may listen to his own words by throwing a lever from the dictating position to the reproducing position.

The Transcribing Machine. Although similar to the dictating machine in appearance and identical in fundamental construction, the transcribing machine is entirely different in function. It reproduces word for word what has been dictated upon a cylinder.

Beginning the operation of the machine the typist places the receivers on her ears, touches the control device, and listens to a number of words. She has complete control of the machine and may cut off the dictation while typewriting the words she has heard. Any word or phrase that the operator does not catch the first time may be repeated as often as necessary.

The Shaving Machine. This machine operates upon the same principle as a lathe where the object is mounted on the machine and rotated, while a tool thrust against it shapes it down, usually to some circular form. In the case of the shaving machine a cylinder is placed upon the mandrel and the knife adjusted to shave off the engraved surface.

The cylinder is placed on the mandrel just as it is on the dictating and transcribing machines. As the knife moves along the cylinder, it shaves off a very fine layer of the wax, thereby making the surface of the cylinder perfectly smooth so that it can be used again for dictation. Each cylinder may be used over and over again—often as many as one hundred times.

Uses and Advantages of Dictating-machine System. Unlike many other office machines, the dictating machine is used in any kind of business, of any size, and in any department. While the more usual applications are found in the handling of office correspondence, there are many other uses which can as easily be made of it. For example, the Irving Trust Company, of New York City, installed a dictating machine in the automobile used by the representatives of the Bond and Mortgage department. It is the duty of these men to go about inspecting properties on which the bank has made loans. Instead of making notes after they finish an inspection or trying to remember all the details until the end of the day, the inspector simply dictates his reports in the machine while being driven from one location to the next. When he returns the cylinders are given to a transcriber and the typewritten reports are ready for signature at the end of the following day.

Considerable use is made of the dictating machine in recording important telephone conversations. Again, instead of trying to remember all of the details of an arrangement which may be made over the telephone the executive may dictate to the machine at the same time that he is talking over the telephone or immediately thereafter. The cylinder is then transcribed later at the convenience of the operator.

Typewriters. It perhaps may seem unnecessary even to mention typewriters in this discussion. Certainly we all know what they are and what they do. The standard typewriter, the noiseless, the portable, and the electric are all familiar. Combinations of the typewriter with calculating machines in the form of bookkeeping, accounting, and billing machines have already been mentioned. The use of the electric typewriter principle in conjunction with the writing of form letters on a duplicating machine will be discussed under the heading of duplicating machines presently. The use of the typewriter in conjunction with the telephone correspondence dictation has received considerable publicity recently. The development of typewriters connected with long distant telephone wires, for the rapid transmission of lengthy messages between offices located in distant cities, is merely another adaptation of the same fundamental mechanism. Suffice it to say, therefore, that of all office machines the typewriter is without doubt the most extensively used. It was the forerunner of most of the other office machines which in turn themselves are now in wide use and it seems destined to continue in predominating leadership for years to come.

Duplicating Machines. The typewriter, just discussed, is of course a form of duplicating machine. Similarly, addressing machines which are taken up in the following section, may be classified under the general heading of duplicating equipment. For our purpose, however, we shall define duplicating machines as those whose function it is to reproduce exact copies of printed, typewritten, or hand-written matter for any purpose. This definition therefore, includes the reproduction of such things as notices, letters, bulletins, reports, charts and graphs, maps and drawings, etc.

Kinds of Duplicating Processes. Five processes of making multiple copies are used, namely, stencil, gelatine, typesetting, automatic typewriter, and photographic.

Stencil Duplicators. Exact reproductions of typewritten work, as well as of maps, charts, in fact, any kind of drawings or illustrations, can be had with stencil duplicators. The stencil is placed in a typewriter from which the ribbon has been removed so that the letters are cut instead of being printed, thus exposing the fibers through which the ink can pass when the stencil is placed on the machine. By means of a stylus, illustrations and drawings and handwritten matter may be stenciled.

The design of these duplicators embodies a hollow, perforated, revolving cylinder partially covered with an ink pad. The ink is applied to the inner surface of the cylinder and passes through the perforations to the pad and openings of the stencil.

To make the copies, the stencil is fastened to the cylinder over the ink pad. A turn of the handle causes the cylinder to revolve, thus bringing the stencil in contact, under light pressure, with the paper which has been fed to the machine. The ink, by capillary attraction, passes through the letters or designs cut in the stencil to the paper, making an impression. Removable cylinders, allowing for the substitution of another when it is desired to reproduce two colors, are found on various machines.

One machine is equipped with automatic feeding devices which bring a sheet of paper to the cylinder with each turn of the crank; others are fed by

hand. With the automatic duplicator, from 1,500 to 5,000 copies can be made in an hour.

Gelatin Duplicators. This class of duplicators makes copies by transferring the ink from a typewritten, handwritten, or drawn original to a duplicating composition which dissolves and holds the ink on its surface until all the copies have been run off.

When preparing the original, hard bond paper and a special kind of ink are used. This may be in the form of a duplicating typewritten ribbon, a duplicating ink, or even an indelible pencil. Different colors may be combined on one original.

This type of duplicator consists of a flat printing bed over which is stretched a gelatin-covered roll. After one surface of the roll has been used, a fresh one may be brought into position by the turn of a handle.

The original is placed face down on the copying surface and smoothed with the palm of the hand or a roller provided for that purpose. It is then lifted off, having left its impression on the gelatin. The blank sheets are placed one at a time on the gelatin surface and allowed to remain a few seconds until the imprint is made.

Typesetting Duplicators. Duplicating machines which utilize the typesetting principle are of two kinds. One prints from typewriter type, the other from standard printer's type, electrotypes, or plates. Certain machines combine both.

The letter, or whatever is to be reproduced, is set up in the typesetting unit which consists of three type banks mounted on a metal frame. A three-bank typewriter keyboard controls the electrically indexed die carrier which embosses the characters on a thin aluminum ribbon. The ribbon is cut off at the end of each composed line and the strips are pushed into position on the disc which fits over the drum of the duplicator. When a complete letter has been composed, the disc is placed on the drum of the duplicating machine and the letter run off. The strips are then removed.

When the type has been set, the printing segment is locked in place on the machine and covered with a broad typewriter ribbon. As the printing drum revolves, each line of type comes in contact with the paper as it passes over a rubber cylinder or platen, thus producing an entire facsimile typewritten letter with each revolution. A signature device signs each letter as it is printed. After the letters have been run through, the name and address are filled in on a correspondence typewriter, using ribbons that match in color the shade of the ribbon used on the duplicator.

Automatic Typewriters. This class of duplicators is designed to produce actual typewritten letters rapidly.

The machine consists of a standard typewriter mounted on and operated by an electric mechanism.

The mechanical movements are controlled by a perforated strip of record paper similar to a player-piano roll. This record is made on a specially designed machine which is part of the equipment. The perforator has a standard typewriter keyboard. The letters to be produced is first written by hand and from this copy the typist cuts the record on the perforator. Each perforation represents a character in the typewriter keyboard and is

reproduced by pressing down on the perforator keys. When the cutting of the perforations is completed, the perforated paper is cut off and the ends cemented together to form a roll, which is then placed on the drum, in front of the machine. In the drum are a number of lengthwise slots over which the perforations in the record paper rest. When the machine is started, the drum revolves, carrying forward the record paper which passes under the pins. As a perforation passes under a pin, the pin drops into a slot in the drum. By means of a mechanical connection this process actuates the typewriter keys as though by hand, and after all the perforations have passed over the drum once, the operator removes the finished letter and repeats.

The machine may be used as any standard typewriter, and at any point the operator may stop the automatic mechanism and typewrite, by hand, information of interest only to the recipient of that particular letter.

Photographic. Deeds, contracts, mortgages, maps, drawings, orders, letters, invoices, testimonials of all kinds can be reproduced in exact duplication.

The photocopying machine resembles a large camera. It is constructed to photograph direct upon sensitized paper which through a process of developing within the machine becomes the finished print. Directly below the lens of the camera and attached to the framework of the machine is a glass-top copy or subject holder. The material to be photographed is placed under the glass.

As the focusing is automatic, little skill is required on the part of the operator. The developing is automatic also. The sensitized paper is held within the machine in a continuous roll and is fed through the exposing chamber, the developing and "fixing" solutions, and then it is cut off at the desired length.

A new development is a machine which is widely used for photographing checks. The equipment for this service includes a camera that photographs checks, or other papers, on a roll of 16-mm. safety motion picture film. Accompanying the camera is a special projector with self-contained screen, on which enlarged negative images of the photographed papers can be projected at will. A 100-foot reel of film not much bigger than a package of cigarettes records 8,000 checks. As a check is dropped into the hopper, it touches the back of the hopper, which actuates the camera in the machine. Thus, by a single movement of the hand, a permanent photographic copy is made. An experienced operator can photograph checks at the rate of 125 a minute.

Field of Duplicating Equipment. In addition to the usual office applications, there are many other commercial uses for duplicating equipment. Cable wrappings, for instance, have the name of the manufacturer and the date printed at intervals of six inches. There are concerns who print their names and detailed information regarding different kinds of shingles directly on the sample shingle. Manufacturers of fabric gloves and mitts use such equipment to print trade-marks and sizes on the cuffs of gauntlets. Cap manufacturers print caplinings with the equipment. It is used to print and sometimes to overprint cellophane, glassine and ordinary paper bags.

One of the largest manufacturers of rubber goods and rubber footwear uses highly developed special equipment of this kind in its production department.

Advantages and Disadvantages of Duplicating Equipment. The advantages accruing to a company which uses duplicating equipment are numerous and obvious. Where many copies of a single letter, report, notice, etc., are needed, the use of a duplicating process of some kind is essential. The disadvantages, or perhaps one might better say dangers to be guarded against, are two. First, be sure that there is a sufficient volume of work to make the investment in a machine of your own economical. If the only need for a duplicating machine is to send out 100 bulletins a month to salesmen, or a similar number of letters to customers and prospects, it may be better to send the work out to a letter shop. This may seem elementary but there are many cases in which machines have been purchased with no more use for them than just this. Second, there is the difficulty of getting an exact match between the name and address and the body of the letter. A well-known company rendering a direct-mail service to retail stores obtains a high percentage of favorable responses not only because the letters are well written but because the greatest care is taken to make them mechanically right in appearance.

Addressing Machines. The phrase "addressing machine" is in some ways an unfortunate one in that it fails to indicate to the uninitiated the numerous tasks other than simply addressing which the equipment produced by addressing machine manufacturers will do. In fact, a number of the devices now available are more in the nature of duplicating processes than addressing. Under this heading may be mentioned such jobs as the heading up of customers records, inventory records, personnel forms, ledger pages, etc.; the writing of tax rolls and bills; the imprinting of short messages on postals, wrappers, folders, and swatches; the writing of dividend checks, pay checks, pay-roll sheets, pay envelopes, pay-roll receipts, stockholders' lists and voucher checks; the preparation of production orders, progress records, schedule and routing cards, time tickets; and the embossing or indenting of metal directory plates, machine name plates, motor name plates, employees ledger, shrubbery tags, cream-can tags, etc. More recently an addressing machine company has developed a duplicating machine which combines the preparation of a letter and the addressing of it through the use of regular embossed address plates in such a way that the principle disadvantage and difficulty of securing a good match between the name and address and the body of the letter has been largely overcome. This same company has just started the marketing of a combination printing and addressing machine, which, by passing blank paper from rolls over a series of imprinters, not only prints the body of the form, in regular printer's type, but addresses it at the same time. Your telephone bill is a specific application of this machine.

In connection with addressing, either for sales purposes or others, the manufacturers have developed selecting devices to a high degree. By attaching tabs to the plates or stencils, the machine will automatically select those names to which it is desired to send the mailing piece, passing all other plates through the machine without printing.

Kinds of Equipment Available. There are two basic kinds of addressing equipment available, namely, that which utilizes a metal embossed plate, and

that which uses a fiber stencil. Otherwise in general principles of operation both methods are similar. The metal embossed plate has, in general, found wider acceptance, especially in the larger companies where the letter duplication attachment feature, the selection device, and the new printing mechanism can be used to advantage. The embossing of the metal plate is done on the graphotype, a machine especially made for the purpose, while the cutting of the fiber stencil is done on an ordinary typewriter. In both cases the frame has space for a card on which is shown the same information that appears on the plate or stencil, thus permitting ready identification. In both systems the principle of operation is to pass the plates or stencils over an inking pad, depress them on the envelope or other paper on which the information appearing on the plate or stencil is to be copied, and then release and pass them on it into a tray or holder. Then the plates or stencils come out in the same order in which they are inserted. In each method the basic equipment may be operated either manually or electrically, although the larger attachments, such as the automatic selector, are available on electric operated machines only.

Attachments Available. Interesting as it might be space does not permit of thorough explanations of the mechanical operation of each attachment, although those who contemplate the installation of an addressing machine should consider such points carefully. We shall, therefore, merely list the various attachments available with a brief explanation of the main purposes of each.

Automatic Selector. A machine equipped with this device can be made to skip the printing of certain plates or stencils automatically as they are fed through. The operation of the selecting device is governed by removable vertical filing tabs or boss points in the case of metal address plates and holes or slots in the case of fiber stencils.

Cut-off. This device makes it possible to non-print certain portions of addresses. For example, a stencil or address plate may contain a customer's name, his address, and a salutation. When this stencil or plate is used to fill in a form letter, the name, address, and salutation are all printed. But when an envelope is addressed, the salutation can be automatically "cut-off" and only the name and address will print. Another common application of the cut-off is in the heading of pay-roll forms.

Dater. Some machines are furnished with an attachment which makes it possible to fill in the date at the same time that the addresses are run. When form letters, statements, invoices, etc. are handled by the addressing machines, the dater attachment is invaluable.

Duplicator. This attachment, furnished on certain machines, causes the address plate to be held in printing position for two impressions. It may be used, for example, for heading statements and addressing envelopes to each customer and printing the back and front of time cards.

Automatic Ejector. The ejector is found on certain small hand models. After a form is printed the automatic ejector removes it from the printing point, throwing it into a box at the side of the machine. This device adds considerable speed to the hand models for straight addressing.

Lister. This attachment is constructed to list names, addresses, or other data on proof, blank, and printed sheets, loose-leaf forms, checks, tags, and labels, automatically feeding the forms and automatically spacing the proper distance after each printing.

Hand Spacer. By means of the hand spacer it is possible to leave one or more blank lines at will so that data may be later written or typed between the addressing-machine impressions.

Numbering Devices. On some machines a number attachment prints either consecutively, in duplicate, or in triplicate from 1 to 999,999.

Repeater. The repeat attachment, provided on several models, prints any number of impressions from the same plate or stencil. Some machines are provided with a hand repeating device, others with a foot lever that permits the repeating of any plate or stencil at the will of the operator, while skipping or consecutively addressing the remaining ones.

Skipper. By means of this attachment it is possible to skip any addresses which are not to be printed. All plates, or stencils after printing or skipping, are automatically refiled in original order.

Signals. Some machines can be equipped with a signaling device to inform the operator when the printing of certain groups of names has been completed. It may be desirable, for example, that the operator be informed when all the names in one department have been printed on the pay-roll sheet, so that space can be left between the groups of names in different departments.

Automatic Envelope Feeder. Self explanatory.

Mailer Strip Lister. This attachment for the larger machines automatically feeds and addresses a narrow paper strip from a roll. This roll is later inserted in a mailer machine which cuts and pastes the addresses on publications.

Advantages and Disadvantages of Using Addressing Equipment. Some of the many uses of addressing equipment other than envelope addressing have already been mentioned. Any kind of business with a volume of work large enough to justify the cost of installation finds many uses for such machines. A sufficient volume of repetitive work, however, is essential. If on the other hand, the same name and address is to be used only once, or at most two or three times in a year, hand or typewriter addressing is more economical.

It is also to be remembered that despite efforts by the manufacturers to avoid it, the stencil or plate address on an envelope is usually quickly recognized as such by the recipient. Consequently many direct mail advertising men prefer to have their material which is going to prospects addressed by typewriter or hand, even at a higher cost. So much direct mail literature is thrown in the waste basket anyway, in many cases without even being opened, that advertising managers naturally wish to avoid anything which gives the impression of a mass production effort.

Time-recording Machines. Time recorders are of two general kinds, namely, those in which the card or paper is inserted in the machine as in the case of job cards, or time stamps and those in which the record is made on a paper wound around a drum which is located inside the machine, as in the case of the drum type of in and out recorder. Equipment is either mechanical or electrical.

Uses of Time-recording Equipment. The principle uses of time-recording devices are:

1. *In and Out or Attendance Record.* In this case the employee usually registers his time four times a day, when he arrives in the morning, when he goes out at noon, when he returns, and when he leaves at night. Either card recorder or drum dial recorder are used. The dial type has the advantage of making it very easy for the pay-roll department to make up the pay roll.

2. *Job Recorder.* The chief use of the job recorder is in the factory where it is necessary to know the time spent by each employee on each job number upon which he works during the day.

3. *Time Stamps.* Hand- and electric-operated time stamps for stamping incoming mail and other papers by departments or for the company on a whole are widely used. The paper is placed in the machine by the employee and the time recorded either to the minute by stamping, as for example, 9:13 a.m. or within a fifteen-minute period by a stamp which makes a clock-dial style of imprint on the paper. The day's date, month and year are also imprinted in both cases.

Other Office Machines and Appliances Available. In the foregoing discussion we have named the principle kinds of office machines and appliances, described briefly and non-technically their chief component parts and mentioned uses and applications. Yet there are more than a score of additional machines and appliances, many of which are to be found in every day use in almost every office, of which no mention at all has been made. Important as these are, space does not permit of anything more than a listing of them. Among these may be mentioned:

1. Check protectors, writers, certifiers, endorsers, cancellers and signers.
2. Autographic registers and manifolders.
3. Credit registers.
4. Scales.
5. Loose-leaf equipment.
6. Bailing presses.
7. Calculation rulers.
8. Coupon-printing machines.
9. Envelope moisteners.
10. Eyelet fasteners.
11. Floor-scrubbing and polishing equipment.
12. Folding machines.
13. Imprinting presses.
14. Multiple stamps.
15. Numbering machines.
16. Paper-cutting machines.
17. Paper punches.
18. Perforating machines.
19. Receipting coupon cutters.
20. Telephone indexes.
21. Ticket-marking machines.
22. Envelope openers.
23. Hand stamp affixers.
24. Parcel-post machines.
25. Sealing machines.
26. Combined sealing and stamping machines.

27. Metering permit machines.
28. Non-metering permit machines.

Conclusion. A discussion of office machines and appliances would scarcely be complete without some reference to the question of selection, replacement and obsolescence. What is the best practice in regard to selection? Are there any tests which can be applied to three manufacturer's makes of book-keeping machines, for example, which will clearly indicate the one best suited to the work to be done? When is an office machine obsolete? Assuming no changes in basic mechanical features—which incidently is not as broad an assumption as some equipment manufacturer's advertisements would sometimes lead one to believe—how many years of service should one expect to get from a machine in a given class before trading it in?

Especially in the matter of selection, one might expect to find a number of companies whose practices could well serve as models. However, even among the large corporations, whose annual expenditures for office machines and appliances run into many thousands of dollars, there is apparently a surprising lack of any really scientific method. Take two or three specific cases. In one nationally known company typewriters were selected for the central transcribing department strictly on the basis of the wishes of each operator. When asked why this was done the office manager said that he thought they were about all alike anyway, so why not keep the girls happy and let them have what they wanted! Another company even larger than the first automatically trades in certain of its equipment at the end of two years, regardless of condition, severity of usage, cost of repairs during the period, etc. A third company recently changed the make of filing equipment it buys, at an increase in cost of approximately fifteen per cent, merely because the president of the equipment company told the president of the using company at lunch one day that he thought they ought to get the business. So far as the writer was able to learn, there was no reciprocity involved in this case, just friendship. The general sales-promotion manager of one of the largest office appliance and equipment manufacturers told the writer that from his observation he believes 95 per cent of the office equipment purchased is bought without adequate investigation and test. He cited on an illustration a corporation of international standing with numerous branch offices, one of whose officers decided that the office equipment problem was large enough to warrant the employment of a man to do nothing else but investigate and advise regarding its purchase. Such a man was employed and lasted less than a year, not because he proved incapable, but because his recommendations remained just that. Friendships, personal likes and dislikes, price, and other similar factors were given first consideration when it came to actual decisions on what to buy.

In the matters of selection and replacement, therefore, specific cases of companies which are doing an outstanding job are not numerous. Production capacity, operating speed, upkeep costs, and normal length of life are all factors which can be ascertained with considerable accuracy. Limitations as well as advantages should naturally be considered. Necessary changes, if any, to be made in the system of record control, forms to be used, etc., should

be given most careful thought. In other words look before you leap, get all the facts, don't take a parrot-like attitude in buying office equipment. These suggestions, which are after all just common sense, seem to be as near as we can come to laying down any scientific principles of selection and replacement.

The August, 1930, issue of *System* gives some thought-provoking facts about obsolescence and replacements in the office machine field. On the basis of a 20 per cent annual depreciation rate as the average used by companies covered in the survey, it was found that 50 per cent of the typewriters, 30 per cent of the dictating equipment, 29 per cent of the duplicating equipment, 55 per cent of the adding and calculating machines, 34 per cent of the folding machines, 40 per cent of the cash registers, 35 per cent of the addressing equipment, 51 per cent of the photographing equipment, and 31 per cent of the bookkeeping machines were obsolete. The article concludes with a statement which may well serve as a conclusion and summary of the basic thought behind this discussion.

Certain changes have taken place in the last five years which not only make our figures (referring to those just quoted) conservative but which, if generally adopted, would result in enormous savings in office management. Now is the time for office managers to adopt the same attitude as factory managers on the question of keeping up with the times.

CHAPTER III

OFFICE PERSONNEL

OFFICE EMPLOYMENT TESTS

By L. J. O'ROURKE, *Director of Personnel Research, U. S. Civil Service Commission*

Office duties may be divided into two general classes—those requiring proficiency in certain lines, such as stenography, typewriting, bookkeeping, etc., and those which do not require a specialized knowledge, but which require ability to learn readily and to adapt oneself to tasks which may require accuracy, speed, judgment, or so-called special aptitude.

The different types of tests used for such selection may be similarly classified as: (1) proficiency tests, such as typewriting, shorthand, or bookkeeping tests; and (2) capacity tests, including (a) general adaptability tests, and (b) special tests.

We can test proficiency in typewriting, in stenography, in bookkeeping, in comptometer operating, etc., with a high degree of validity¹ and reliability,² provided the tests used for any one of these types of work are properly constructed, made exactly comparable in difficulty, standardized, given under standardized conditions, and properly scored. Under these conditions, a given score on one series of a test may be reliably compared with any other given score made by any other person at any other time on any other series of the test.

Capacity Tests. Measurements for determining capacity—ability to learn and adapt oneself to new duties—are more difficult to devise and standardize. It is easier to determine the speed and accuracy at which a trained person can at present perform a standard task on a calculating machine, than it is to predict the speed and accuracy with which an untrained person would be able to learn to perform that task. It is therefore easier

¹ In this paper the term *validity* of a test shall be used to indicate the degree to which the test measures the ability it is designed to measure. If there is little relationship between the scores made by persons on a test designed to measure ability to do a certain task, and these persons' relative known ability to do this task, we say that the test has little validity. If the relationship between test scores and known ability is high, the test has high validity.

² The *reliability* of a test is the extent to which it consistently measures what it measures, i. e., the extent to which persons would be ranked in the same relative order by their scores on alternate forms of the test, quite apart from the relation of those scores to anything else.

to construct means of measuring, with a high degree of validity and reliability, an individual's proficiency, speed, and accuracy in stenography and type-writing, than it is to develop tests for predicting the extent to which persons will satisfactorily perform a variety of clerical tasks.

A further difficulty in the development of capacity tests for clerical work is the fact that it is difficult to measure output and to secure valid and reliable efficiency ratings by means of which the diagnostic value of the tests can be determined. When valid efficiency ratings are attainable, it is possible, after a careful analysis of the job, to construct capacity tests which indicate ability with a high degree of accuracy and reliability, as will be demonstrated later.

Research in selection embraces both the construction of devices for measuring the different abilities which are required for various positions, and the testing of these devices. A detailed study of the duties performed is necessary in connection with each of these selection problems.

The study of duties will include determination of the qualifications required for their performance. It is then necessary to determine what is the best method of evaluating and recording relative efficiency of employees in that particular work—whether by means of production records, by personal judgments of supervisors, or by some specially devised procedure.

The relative efficiency of employees must be determined in order to test the tests—that is, in order to determine whether those who make the high scores on the examinations developed are those who are most efficient in the performance of the work, and those who make low scores are relatively less proficient in the work.

The detailed study of duties necessary in constructing and evaluating an examination is also essential to the person engaged in developing training procedure for the position in question. Likewise, a study of these same fundamental factors is necessary in solving problems of promotion, of transfer, or of wage adjustment, and in understanding the relations between employees and management. If an analysis such as is necessary for any one of these purposes is undertaken without consideration of the other problems of management, the material developed can seldom be utilized in handling the other problems.

The duties of each type of position being studied should be so thoroughly analyzed, under actual working conditions, that the results will form a basis for reducing fatigue and conserving the energy of the worker, and for improving methods of training, transfer and promotion procedure, wage adjustment, organization of work, and coordination of activities, as well as for evaluating the tests and other data involved in research programs. The values derived will, in most cases, more than justify the research work, irrespective of test results.

Valid Tests of Capacity Illustrated. An example of valid tests of capacity are the tests which we have devised to select postal clerks. Analysis of the work of distribution of mail in the post office showed that the clerk must memorize some two to five thousand names of cities before he begins the work of distributing mail. In distributing, he must keep in mind that at certain hours of the day, mail which at other hours goes into compartment 3 of his

distribution case, now, because of different train connections, belongs in compartment 7. From time to time locations of postal stations change, as do mail routes. He must, therefore, be able to inhibit the tendency to place certain letters in compartments 3 or 7, and must recall that, to make different connections, these letters now go into compartment 8. Our mail clerk's problem, then, is to memorize these 5,000 names, to keep frequent readjustments and changes in mind, and yet to distribute very accurately and very rapidly.

Since the entire study is covered thoroughly in one of our annual reports,¹ I shall discuss here only the nature of the tests used to measure the capacities which analysis of the duties showed to be necessary, and to the criteria used to determine their validity.

Of the fifteen tests which we tried, the most effective one was a simple substitution test which requires the competitor to study for ten minutes a list of names, making mental associations between those names and key numbers, and thereafter to substitute the correct number for each name in the test list. As the competitor continues to make these substitutions, his task is simplified in direct relation to his ability to form the associations.

Comparison of differences in employees' test scores and differences in their efficiency ratings showed that this test, which we call the "sorting test," is excellent for predicting the applicant's output as a distributor in the post office. Applicants differ widely in the number of items which they answer in the time allotted, this number ranging from 20 to 350.

The test ranking next in selectivity was a "following instructions" test, which measures differences in the degree of accuracy with which competitors are able to follow directions in making changes in distribution schemes and in routing. That each of these tests measures qualifications essential for success in the job is demonstrated by a correlation² of 0.503 between efficiency ratings and scores on one of the tests, and by a correlation of 0.647 between efficiency ratings and scores on the other test.

The predictive value of this battery of special tests is indicated by a correlation with the criterion of 0.65 in the first trial, 0.67 in the second trial, and 0.69 in the third trial.

These special tests measure qualifications required for performing the duties of clerks in the post office much better than do the general tests. By general tests I refer to what is popularly known as the intelligence test. Scores on the test of general intelligence correlated with the criterion in the first study 0.44, in the second study, 0.37, and in the third study, 0.40. However, the addition of the general test to the battery of special tests increased the correlation from 0.69 to 0.715.

What does a correlation mean in terms of selection value in any specific case? Looking at this correlation chart (Fig. 1), which is only a sample and has no connection with the postal tests to which I have referred, we find

¹ Forty-second Annual Report of the U. S. Civil Service Commission.

² For practical purposes, think of the coefficient of correlation as the mathematical expression of the relationship found between any two variables, such as test scores and efficiency ratings.

that efficiency is represented horizontally—low efficiency at the left, high efficiency at the right. In studying the effect of dividing the group on the basis of various test scores, we find that, of the 18 persons scoring higher than 80 on the test, 17 are to the right of the center line. Seventeen persons who made this score proved to be better than average in efficiency, one lower than average in efficiency. The coefficient of correlation—0.61—by itself would not indicate this high and significant relation between high test scores and success on the job.¹

We also find that, of the 25 persons scoring between 60 and 80, 13 are above the average in efficiency. That is, there is a fifty-fifty chance of getting efficient employees from this group.²

FIG. 1.—Test score showing low efficiency at left and high efficiency at right of chart.

Of the 18 persons scoring below 60, 2 are above average efficiency. For the applicants in this group, the odds are 8:1 against their proving of better than average efficiency.³

I have introduced this example to show that the coefficient of correlation should not be considered the sole indication of the value of a test. Its value is also determined by the point at which the passing mark is set. The distribution of cases on the scatter diagram must be given careful study.

What the statistics I have cited in connection with the postal tests mean in actual results is indicated by a careful follow-up study which showed that

¹ This does not mean that the exact 17:1 ratio would hold for another group even though one-third of the group were above 80 and the correlation were 61.

² A ratio close to fifty-fifty would be likely to maintain.

³ The statement in footnote 5 applies to this ratio.

93 per cent of the employees hired after the new examination was adopted were superior to the average of the employees selected by tests of geography, spelling, arithmetic, and letter writing. The significance of this superiority is more apparent when it is realized that vacancies in the large majority of the 300,000 post office positions are now being filled by the use of the practical tests which more directly and accurately measure essential qualifications.

Each of the three tests selected for actual use from a battery of fifteen meets the following specifications:

1. It measures qualities essential for success in the position.
2. It measures qualities not measured to the same extent by other tests in the examination; that is, it adds to the selective value of the examination as a whole.
3. It differentiates among different degrees of ability; that is, it distinguishes qualified applicants from those who are not qualified, and differentiates among the degrees of aptitude for the work. (a) It is focused at the correct difficulty; (b) it is of the correct range of difficulty.
4. It is reliable, that is, it is such that a competitor will make approximately the same grade on any alternative series.
5. It can be readily duplicated.
6. It is objective (a) in administration, (b) in scoring.
7. It is practicable (a) in its appeal to the applicant, (b) in time required and facility in administration, (c) in time required and facility in scoring, (d) in cost of printing.

The criterion¹ used in this study of tests for selecting postal clerks consisted of three factors:

1. The average number of pounds of first-class mail distributed by each employee during a period of six months, together with the amount of time, in minutes, spent on this distribution.
2. The records in a monthly case examination. This examination measures the rate and accuracy with which each worker can distribute into his distribution case.
3. Foremen's ratings based on a combined graphic and man-to-man rating scale.

The results attainable in the process of securing the desired measurement of efficiency are well illustrated by an example which A. C. Farrell, of the Dennison Manufacturing Company, cited in a paper before the American Management Association.² He said:

Our standard for transcribing from dictaphone cylinders is expressed in terms of a standard line of approximately six inches in length and averaging ten words per line. One hour time allowance for each 120 lines is the standard for this work.

The standard output per day of 8¾ hours, less 10 minutes for rest periods, is 1,030 lines. The average qualified operator will turn out between 1,400 and 1,600 lines per day, and an exceptional girl's production will run as high as 2,000 in a day.

¹ The criterion is our measure of the relative degrees of ability possessed by persons as indicated by their success on the job. Think of it as efficiency ratings.

² "Measuring Office Output," *Office Executives' Series*, No. 32, p. 10, 1928.

These first studies showed such a great possibility of saving that none of us who were in charge of that department could believe that it would be possible. We thought that no group of clerks could so increase their production. For one thing, according to the standards then established, but two of the book-keeping machine operators out of a group of eleven were attaining as high as 80 per cent. Please remember I said that 100 per cent, the standard, represents a minimum, not even an average rate of production. Today there is no operator in this department who is averaging less than 125 per cent and one girl has gone as high as 167 per cent for a full week's work.

The eleven operators have been reduced to seven, with the consequent release of expensive equipment.

The job analysis to which Mr. Farrell refers was undertaken as a basis for establishing standards and rates of work. It differs in objectives, rather than in methods or results, from analyses which are made as a basis for standardizing selection methods.

Such a study as reported by Mr. Farrell offers a basis for securing a valid and reliable criterion. Let me repeat that if no study has been made for establishing standards and rates of work, a study designed to secure a criterion affords an excellent opportunity for making such a contribution, quite apart from the success or failure of the test program. This is why work studied should be undertaken with the broader objective in mind, and not merely for the purpose of testing a test.

The extent to which an analysis of the latter type may result in relieving unnecessary expenditure of energy, yet may, at the same time, increase production and lead to better relations between management and employees is demonstrated by a study of the work of postal clerks.

Attention was called to the need of a new type of examination for selecting men for one type of mail distribution in one of the large post offices. The new examination was thought necessary because of the difficulty of securing efficient men for this work. In order to measure the abilities required for this particular type of work, not general throughout the post office, it would have been necessary to devise special aptitude tests and motor coordination tests requiring complicated equipment. Had effort been devoted immediately to the development of such tests, the particular problem assigned—that of devising a means for selecting efficient men for this work—might have been solved. On the other hand, great expense for equipment and for test construction and administration would have been involved, and the working conditions would have continued to demand men able to withstand excessive strain.

When a study of the type of distribution work described was undertaken, it was found that the task which required considerable skill and two or three months of training, and which involved excessive strain, could be changed to a much simpler task requiring no particular skill or endurance. This change was recommended, and the construction of expensive equipment and special aptitude tests was made unnecessary.

Naturally this change greatly simplified the problem of devising selection tests. The results of the study, however, were of far greater importance in simplifying the problems of management. Turnover has been reduced,

output increased, and morale improved as a result of the analysis which should precede a test program.

Differences in Correlation between Test Scores and Criterion. What are some of the reasons for conflicting reports as to relationships between test scores and criterion, as evidenced by great differences in correlations reported? This is answered in part by first answering the question: How are we to decide what factors to include in our criterion, and how to weight them? A criterion should consist of the factors contributing most to the employer's satisfaction or dissatisfaction with the way in which the duties of the position are performed. In studying any given position with a view to securing valid ratings of the efficiency of the persons employed in the work in question, we should, as one of the initial steps, ascertain the reasons for employees' succeeding or failing or becoming problem cases. Incidentally, the basis of complaints or of difficulties encountered with employees should be ascertained. Such a study will form the basis for deciding which factors are to be included in the criterion, and the importance to attach to each factor. At the same time, it affords a clearer understanding of the factors that tend to improve or to weaken morale.

To illustrate, let us consider two groups of stenographers. Those in Group 1 take dictation in shorthand, and transcribe the notes exactly as given, the subject matter consisting of non-technical letters and reports. The stenographers in Group 2 take shorthand notes, and compose letters and reports from notes; they meet callers, handle inquiries, make appointments, and perform other secretarial duties. Let us list the factors that might determine the efficiency ratings of the two groups of stenographers.

a. Stenographic speed, stenographic accuracy in taking and transcribing dictation.

b. Typing speed, typing accuracy.

c. Ability to write intelligent and correct letters from notes—this ability involves judgment and knowledge of spelling and grammar. Suppose we call it general stenographic requirements as distinguished from stenographic proficiency.

d. Cooperation, industry, effort, initiative, ability to accept criticism, ability to meet people—that is, to make people feel that they are receiving courteous treatment and consideration—and tact in so handling difficult cases that resentment is relieved rather than created.

Let us consider the importance, in terms of success and failure, of the factors listed. We find that for Group 1, the group doing principally stenography and typing, speed and accuracy in taking dictation are definite factors in their being rated as satisfactory or unsatisfactory. For Group 2, while stenographic speed and accuracy are obviously essential, few of the group are rated unsatisfactory or are discharged on this score. It is not, therefore, a serious problem for Group 2.

Next, we consider ability to write letters from notes. The stenographers in Group 1 are not required to compose letters and reports or to exercise a high degree of judgment in their work. Consequently, few are discharged or rated low because of lack of ability to compose letters. It is not a problem in their case. On the contrary, we find that many in Group 2 fail because of

lack of this general ability, and hence it is a very important element in their efficiency rating.

For Group 2, all the personality factors are important. For Group 1, none of them are essential, with the exception of industry and effort, and the stenographers of this group are closely supervised with regard to this point. These stenographers have little occasion for initiative; they do not meet the public. The members of Group 2, however, to a great extent, work on their own initiative, their effort is largely unsupervised, and they are required constantly to meet new people. A few marked cases of inability to cooperate, inability to accept criticism, lack of initiative and effort are noted, and people are discharged on these scores. These are usually, however, very pronounced cases, and as such they leave a very definite impression upon employers. Their importance, therefore, is likely to be exaggerated. As a matter of fact, a check of the efficiency records shows that, though separations on these scores are more likely to be remembered, the personality factors are less a problem, even for Group 2, than are the other factors.

As a result of our analysis, let us consider the following weights which management might reasonably assign to the four main classifications of the efficiency ratings of stenographers.

For Group 1, we could give stenographic speed and accuracy a weight of 45 out of 100 points; typing speed and accuracy, 35 points; general stenographic requirements, *i.e.*, judgment, the ability to spell and use English, 15 points; and personality factors, 5 points.

In contrast, for Group 2 we could give stenographic speed and accuracy a weight of 30 points; typing speed and accuracy 20 points; ability to write intelligent and correct letters, 35 points; and personality factors, 15 points.

Obviously, the correlation between the efficiency ratings weighted for Group 1, and scores made by Group 1 on a battery of stenographic, typing, spelling, grammar, letter writing, and judgment tests, would be quite different from the correlation between the efficiency rating weighted for Group 2, and scores made by Group 2 on the same tests. The judgment test may be expected to have a low correlation with the criterion for Group 1, where judgment factors are given a weight of only 15 per cent in the criterion, but a higher correlation would be expected with the criterion for Group 2, where these factors are given a greater weight than any other factors.

This brief analysis shows why we can not talk in terms of relative value of tests for a position, merely by naming the position, without considering the nature of the duties, and the relative importance of the efficiency factors as weighted by employers.

One of the reasons, then, for the conflicting reports as to relationship between test scores and efficiency is that the criteria—usually efficiency ratings—used in different studies, are based upon different factors. The significance of test scores naturally differs when these scores are compared with different factors. Sometimes the criterion refers to routine work; at other times it refers to work requiring more judgment. Sometimes, in rating efficiency, accuracy is given a much greater weight than is speed; sometimes the reverse is true. Sometimes the criterion is based upon actual production records, and such factors as interest, effort, personality, etc.,

have no part in it. In such cases, a higher relation should naturally be found between efficiency and scores on carefully constructed tests than when personality, temperament, and other general factors, which the test does not measure, enter into the total efficiency rating. In other words, the factors reported as office efficiency, by various personnel men, differ almost as widely as do the relationships which are reported between test scores and office efficiency.

Suppose we are evaluating a battery of general tests for selection of clerks. Let us suppose that on certain groups of clerks we have reliable and valid efficiency ratings based on the following factors: effort, cooperation, speed, accuracy, judgment, absence, and tardiness. Let us assume, also, that analysis has shown that these are the factors which should constitute the criterion for this type of clerical work. Let us next consider that we have found the correlation between the scores on the battery of four tests, properly weighted, and the total criterion, and that the correlation is 0.48.

Next, we should find the relation between the total scores and that part of the criterion which has to do with speed, accuracy, and judgment, which most definitely relate to output and ability; let us suppose that the correlation between the four tests, properly weighted, and this part of the criterion is 0.64.

It is important for us to know that the tests predict success and failure as a whole, when the entire criterion is used, to the extent indicated by a 0.48 coefficient of correlation. We should not, however, be misled by this coefficient. It is even more important for us to realize that the tests are designed to measure and predict speed, accuracy, and judgment, and that they do predict this to the extent indicated by a 0.64 coefficient of correlation. Moreover, it may be possible by the use of reliable personal history records, application blanks, references, etc., to increase our ability to predict effort, cooperation, absence, and tardiness, and thus increase the value of the total prediction for each of the divisions of our criterion.

Importance of Criterion in Choice or Construction of Tests. The criterion should be considered not only as a means of measuring the effectiveness of tests, but also as a means of determining what tests to make or to use. If analysis of the position shows clearly that speed, or accuracy, or memory, or ability to compose an effective letter, or ability to adapt readily to new situations is essential to success on the job, then not only should that quality be weighted in the criterion, but tests should be devised or selected to measure it, and such tests should form the basis of the battery of tests used in the research program.

Stenographers differ more in judgment, knowledge of spelling, and ability to use English, than any of us would believe. I was requested recently by one of the managers of a large organization to test stenographers and typists in that organization. The general complaint was that a great many of them were unable to "use their heads." They had been selected previously on the basis of a written test in stenography and typing. The test also included some spelling items and a letter which was evaluated in the more or less subjective way in which letters are generally evaluated. There was no general intelligence test, so called, used in their selection.

I gave to this group our new classification test for stenographers and typists. This test is made up largely of judgment items; it contains, in addition, 20 non-dictated spelling items and 20 multiple-choice grammar items. The scores of the stenographers and typists ranged from 16 to 85. The scores were scattered about equally along the scale, some two or three points apart. For example, the lowest score was 16:

1 had a score of 20	3 had scores between 56 to 59
1 had a score of 24	5 had scores between 60 to 63
2 had scores between 28 to 31	2 had scores between 64 to 67
2 had scores between 32 to 35	4 had scores between 68 to 71
5 had scores between 40 to 43	4 had scores between 72 to 75
4 had scores between 44 to 47	2 had scores between 76 to 79
6 had scores between 48 to 51	6 had scores between 80 to 83
2 had scores between 52 to 55	1 had a score of 85

The significance of this scattering of scores from very low to high becomes apparent when the same decided trend is found to exist in the efficiency ratings of these employees. Those who made the lowest scores proved to be those with lowest efficiency ratings; those with scores about the average of the group were those whose efficiency ratings are about average; and those whose scores were highest were those who have the highest efficiency ratings. The coefficient of correlation between scores and efficiency ratings was 0.73. Of the 25 per cent who made the highest scores, approximately 90 per cent were above the average efficiency of the group.

To be sure, personality factors contributed to the complaints regarding these employees, but the major reason for dissatisfaction, as determined by a comparison of test scores and efficiency ratings, was lack of judgment, lack of ability to use English, and, to a lesser degree, faulty spelling. Many cases of supposed lack of interest, effort, and initiative, were in reality, as evidenced by the low scores, lack of ability.

I do not mean to minimize the importance of effort, interest, initiative, and so forth, as important factors in determining success and failure. I realize the importance of these factors. I realize, also, the difficulty of predicting or evaluating them. My point is that there are important qualifications that we *can* measure. Measuring these will often help us to judge such factors as effort, interest, and so forth. It is only practical, then, to concentrate effort on measuring, by means of objective tests, the measurable factors. Certainly we have as much reason to expect cooperation and initiative from those with superior abilities as from those with less ability.

The main reasons why conflicting reports are so often given in regard to the relation between efficiency and test scores and other data are as follows:

1. Those evaluating tests include different factors in their efficiency ratings for the same class of positions. Therefore the correlation between test scores and these different efficiency ratings might well be expected to be different.

2. Different factors in efficiency ratings are often given different weights by different raters. The relation between test scores and efficiency ratings will vary according to the weights assigned to the factors making up the efficiency rating.

3. Examiners often use tests which are generally labelled similarly such as "clerical tests," but which, in reality, are quite different, owing to the differences in the range of the test or in the difficulty at which the test is focused.

4. The lower the validity of the efficiency ratings, the lower the correlation with test scores, other things being equal. That is to say, if the criterion has no validity whatsoever, we should expect a zero correlation with test scores, regardless of whether or not the test does measure or predict ability for the position in question.

5. Some persons include in their efficiency ratings factors which the test does not attempt to measure, such as length of service, tardiness, personality, etc. Others include only ability factors which the test is designed to measure, such as speed, accuracy, and so on. Obviously, the second group would find a higher correlation with efficiency ratings than would the first group. Some persons construct tests to measure factors that analyses of duties have shown to be important, while others simply go ahead blindly, hoping that with some of the tests they will find a relation with efficiency ratings.

6. The range of ability of the group tested influences the correlation. The wider the range of ability, the better the correlation. For example, suppose you were asked to observe the work of 20 clerks, whose actual output, as evidenced by production records, ranged from 16 to 85, with a fairly even distribution throughout that range, and to rank the 20 clerks, on the basis of your observations, as nearly as possible in the order of their relative production. It is quite probable that the relation between your judgment and the actual production of the 20 clerks would be high. Suppose, however, you were asked to observe and rank in order of efficiency another group of 20 clerks whose actual ability, as indicated by production records, ranged only from 75 to 78. This would be a more difficult task; your judgment as to their relative ability would show a much lower relation to the facts.

Thus it will be seen that the problem of differentiating among people whose ability is very much the same is much more difficult than that of differentiating among people who differ greatly in ability. We find a much lower correlation when we have a restricted range of ability, and a much higher correlation when we have a wider range of ability. It is, of course, possible, by means of a special statistical formula, to predict, with a high degree of validity, what the correlation would be if the range were greater or less.

7. Some persons determine the weights to be assigned to the various parts of the examination by means of multiple correlations. Others merely weight the tests by guess. Obviously, the correlation between tests and criterion in the second case will be lower than in the first case.

Relation between Speed and Accuracy. We are constantly hampered in the securing of a valid criterion by the fallacious belief in the "slow but sure" worker. Slow workers are rated high merely because of the prevailing idea that they make few errors, and that persons who work more rapidly are less accurate than those who are more deliberate.

What is the actual relation between speed and accuracy in office workers? Let me answer this question with reference to a study which we made of general clerical tests. After a revised general clerical examination had been accepted and used, a study was made of the performance of 500 competitors on a twenty-minute clerical test.

Figure 2 shows the accuracy of the 125 most rapid workers as compared with that of the 125 slowest workers. The percentage of accuracy of each

individual was based on the relation between the number of items correct and the number of items tried. Although some slow individuals are accurate and some rapid individuals are inaccurate, the work of the 125 most rapid com-

FIG. 2.—Comparison of accuracy of 125 most rapid workers with 125 slowest workers.

petitors was 80 per cent accurate as compared with 38 per cent accuracy of the 125 slowest workers.

Figure 3 shows the relative number of items correct, or the production of the rapid workers, as compared with the production of the slow workers. The

FIG. 3.—Comparison of the production of rapid workers with slow workers.

number of items answered correctly by the 125 rapid workers was five and one-half times that of the 125 slow workers, or in the relation of 200 to 36.

Figure 3 also shows the relative number of items answered incorrectly by slow and rapid workers as well as the relative amounts of time required by

the two groups. In accordance with the rates of speed at which they worked, the slow group would have taken 110 minutes to answer 200 items correctly, as compared with 20 minutes required by the rapid workers. In order to answer these 200 items correctly, the slow group would have answered 352 items incorrectly, as compared with 50 incorrect answers by the rapid group. If it were justifiable to speak of answers as production, this would mean that a given task would require five and one-half times as many slow as fast workers, and the spoilage of the slow workers would be seven times as great as that of the fast ones.

These findings are based on the relative value of speed and accuracy for general clerical positions. No generalization is warranted which would attempt to assign this same relation between speed and accuracy as a basis for the selection of applicants for positions requiring different qualifications.

FIG. 4.—Relation between speed and accuracy of employees on monthly case examination.

FIG. 5.—Relation between speed and accuracy of competitors on sorting test.

Similar results were secured in the study of speed and accuracy of Post Office employees. Postal employees are given a sorting test each month as a basis for the Post Office Department's efficiency ratings. This test is designed to resemble the work of sorting as closely as possible and is a very close measure of the relative efficiency of postal clerks. In this test a large number of cards, each bearing an address, either handwritten or typed, are distributed into the departments of a sorting case, according to the same sorting scheme used by the clerk in his daily work. The time required to sort the cards and the number of errors made determine the clerk's efficiency rating.

A comparison was made, both as to speed and as to accuracy, between slow and rapid postal clerks who used the same sorting scheme. The slow group sorted an average of 22.87 cards per minute, as compared to an average of 51.12 per person per minute for the rapid group (see Fig. 4). The rapid group was therefore two and one-fourth times as fast as the slow group.

The total number of errors made by the slow group on this test was 163, as compared to 53 for the rapid group, or three and one-eighth times as many errors for the slow workers as for the rapid workers.

The rapid workers are therefore two and one-fourth times as fast, and make fewer than one-third as many errors as the slow workers (shown by Fig. 4).

We found that the Civil Service sorting test makes a similar distinction among competitors (see Fig. 5). The slow group of competitors completed an average of 10.28 items per minute, while the rapid group completed an average of 27.98 per minute. The rapid group of competitors was therefore two and three-fourths times as fast as the slow group. This is a slightly higher ratio than that given above for slow and rapid employees on the monthly card-sorting test.

FIG. 6.—Extent of differentiation in examination scores.

The total number of errors on the sorting test given to competitors was 108 for the slow workers, as compared with 42 errors for the rapid workers, a ratio of two and one-half to one.

Another frequently recurring question having to do with the factors of speed and accuracy is this: *What is the relation between speed and accuracy scores on tests, and actual performance on the jobs?* This question, too, can be answered with a report of one of our studies—the post office study which has already been mentioned. In a final study made in order to verify the value of the new post office examination, the tests, with samples, exactly as printed for actual use, were given to a group of 124 employees of the mail department in the Chicago Post Office, for whom accurate efficiency records were available.

The extent to which the examination scores differentiate among the employees is shown in Fig. 6.

The vertical line *OO* is the dividing line on either side of which 50 per cent of the efficiency ratings of the whole group fall. It will be referred to as the average. Each horizontal bar represents one quarter of the group tested. The top bar represents the distributors who made the highest 25 per cent of the test scores, hereafter referred to as group *A*. The lowest bar represents those who made the lowest 25 per cent of the test scores, or group *D*. In each bar, the part at the right of the vertical line indicates the percentage of that group rated above average in efficiency; the part at the left shows the percentage of the group rated below average. The highest 25 per cent in efficiency of the total number of distributors is represented by the solid white, and the lowest 25 per cent of the total number by the solid black part.

This chart shows that of 100 competitors equal in test scores to those of Group *D*, the lowest group, 94 per cent would be expected to be below the average in efficiency of the distributors tested, nearly all of bar *D* on the chart falling to the left of the line *OO*. A low test score is actually indicative of lack of aptitude for the work.

Not more than 25 per cent of the applicants are likely to receive appointments, and we are therefore concerned chiefly with the top bar. This bar shows that those who make the highest test scores are the distributors who

FIG. 7.—Second study of group scored in Fig. 6.

are highest in efficiency. The chances are 91 to 9, or 10 to 1, that their efficiency will be above the average of the distributors who were tested. In other words, it may be seen from the chart that, if 100 competitors made scores equal to those made by Group *A*, 91 will be likely to be more efficient than the average of the distributors who were tested; and 55 of these 91, represented by the solid white part of the top bar, may be expected to be as efficient as the 25 per cent most rapid and accurate of the distributors on whom the tests have been tried. Thus it may be expected that 91 per cent of all the appointees who will be selected through the new examination will be more efficient than the average of the present employees.

These findings were verified in a second study in which 93 per cent of the upper quartile in test scores were above average in efficiency, and none of the lower quartile were above average in efficiency (see Fig. 7).

TRAINING CLERICAL WORKERS ON THE JOB

By W. H. LEFFINGWELL, *President, W. H. Leffingwell, Inc.*

What Is Training? Since training in clerical work is a subject few of us know very much about, and most of us use the term "training" rather loosely, a definition is in order. Education is a term that is constantly confused with training, though there is a decided difference between these two activities. Education signifies the systematic development of the mind and other natural powers, and its aim is to give us a harmonious development of all our faculties. Training, on the other hand, is a much more limited term and may be defined as the development of habits. In the sense in which I shall use the word here, it means the development of work habits in general, and in this case, clerical work habits in particular.

Now in this sense, training is far from being universal in offices. Executives usually do not consider that there is any need of, or any advantage in, the development of specific work habits. Of course everyone recognizes the difference between the trained and the untrained office worker, but there are few executives indeed who can recognize the poorly or partially trained worker, or who are, in fact, interested in anything other than the final result. If that is satisfactory in their estimation, the means by which it is brought about, or the cost of obtaining it, seem to be matters of slight importance to them.

Breaking in the New Clerk. What passes for "training" in the usual office is somewhat as follows: The clerk is brought into a new and strange environment, seated at a desk, and given a batch of work by a person who is a complete stranger to her. Naturally her confusion is great. The supervisor talks to her, tells her about the work, sometimes for as much as an hour. She is miserably self-conscious, imagines that everyone in the office is looking at her and, as a result, hears perhaps about half what the supervisor says. She is then left alone with the work. She tries to remember some of the things she has been told, but with little success, and after mentally floundering around for a time, finally sums up courage to begin. Naturally she makes mistakes—many of them. Her first mistakes are overlooked, but after that they are noticed, and she is disciplined and perhaps threatened with discharge, which threats merely serve to confuse her all the more. However, unless she makes too many errors, the threat is not carried out, and after she has made the usual quota of mistakes that all beginners—under such conditions—must make, a sufficient number of times, and has been duly "called down" in consequence, she is then alluded to as a "trained clerk," a most grotesque application of the term.

Two Methods of Training. In the few offices where attention is given to the subject of training, there are two general methods in use: the vestibule school and training on the job. The former is supposed to give essential training to the new employee, before he—or she—enters upon the actual work of the office. Such training, as a rule, is short, though in some large companies it is repeated at frequent intervals with employees who are being trained for higher work. But this method is applicable only in the very

largest offices, as, unless there is a heavy labor turnover, the number of new employees would be too small to warrant the expense of a training school. And on the other hand, if the turnover continued great in such a company, it would be a very strong indication that the training was inadequate.

Inadequate Training in the Vestibule School. There are indeed two very obvious reasons why the training given in a vestibule school must ordinarily be inadequate. Such a school cannot train clerks for the hundreds of positions to be found in the office, for the reason that teachers, expert in them all, cannot be obtained, the fundamental units not being sufficiently known or classified to be taught as units. Secondly, the time available for instruction in a large number of things is too short, and to lengthen it would not be advisable. As a consequence many of the so-called vestibule schools give but a short course in the rules and policies of the company, and the most meager training in work habits for a few elementary jobs. From then onward, little organized, conscious training is given the worker, though in a few notable exceptions this is not strictly true. There is also a tendency for supervisors of offices which have classroom instruction, to consider that they are thereby relieved from all further training.

Training on the Job. But without question the most effective place to do the training is actually on the job. This method has the great advantage of dealing with realities. The worker at once realizes that he is taking part in the actual work of the company; he sees other workers around him engaged in the same sort of task, his spirit of emulation is aroused, and he is confident that he also possesses the ability to master it. Training on the job is also intensive, and therefore more quickly effective. Work habits can take form directly, and the worker himself can perceive without difficulty their necessity and value.

This method of training can also be continued indefinitely without undue expense, and consequently those who are slow to learn, though really good workers otherwise, are not lost to industry.

An objection commonly raised against training on the job is that a large staff of special teachers is required and that the expense of this is prohibitive. This is simply not true, for out of every group of skilled workers it is usually possible to select one who has the ability to impart his knowledge to others. Therefore it is not necessary to add to the teaching force at all, for the actual workers can be used as teachers, subject to the oversight of the supervisor.

Reasons for Neglect of This Method. In short, training on the job is so undeniably successful and so universally applicable, that one wonders why it is not more prevalent. There are, however, several reasons for this neglect.

1. Training of work habits presupposes standard methods and work habits, but in the large majority of offices there are practically no standardized methods, and where these are non-existent, it naturally follows that there is nothing to teach, and therefore no reason why training should be stressed. Then again, to standardize requires much extensive labor; in fact a huge task that may take years to accomplish completely. For this reason, personnel men have been content to make the so-called job analysis. This, in actual practice, is not what we engineers call an analysis of the job or a scientific study of it for the purpose of improving the operation by the elimination waste but is merely a catalogue of the thing at present being done.

2. Among the executives of this country there seems to be a general assumption that correct habits of work will form naturally with the requisite amount of experience, an assumption that is entirely baseless. It is true that work habits are formed in every case, but they are not alike with different workers, and they are rarely good work habits. One does not learn naturally, for instance, how to lay bricks correctly. A long apprenticeship is necessary, and even then, in this 6,000-year-old craft, the late Frank Gilbreth found, by scientific study of the operation, that of the eighteen movements customarily used by skilled bricklayers, no less than thirteen were wasted and valueless. By the new method he evolved, the output was increased from 125 to 350 bricks an hour, and that, too, with a reduction in the resultant fatigue.¹

3. There is also a general assumption on the part of most office managers that office work is simple, does not require training, and that work habits are matters of no particular importance. But the fact remains that there is no task so simple that the method of performing it cannot be improved by proper study. As I shall show later on, few clerks know the right way to affix a postage stamp on an envelope—apparently a very simple matter.

The difference in results between the average methods of working and the best methods, are, however, so startling that it seems difficult to believe that not all office managers are striving to attain the best. When it can be plainly demonstrated that a trained worker can easily produce twice as much output as the average worker without such training, one would think that every office would establish organized training, but perhaps not one in a hundred has as yet made the barest beginning of such scientific training.

It can be maintained without fear of denial that even experienced clerks do not naturally adopt the best methods; neither do clerks "pick up" best methods by observation. I have seen untrained clerks seated among highly trained operators, yet making no attempt whatsoever to imitate their better methods.

Six Steps in Training Clerks. The problem of training clerks involves considerable study, and is composed of six important steps.

1. The actual work to be done must be explained to the worker in a manner that will thoroughly impress him with (a) the purpose of the work; (b) the relation of the operation to other work; (c) the relative importance of the various details of the job; and (d) the manner in which it is to be done. This is the beginning of all training, and there are perhaps more companies who take this step than will be found taking the rest of them. But it is only the beginning, and nothing remarkable can be accomplished by stopping there.

2. The best arrangement of the work and the work place should be taught. If every job is carefully studied, it will be found that there is always one particular way of arranging the work and the work place, that is far superior to others. But this is a matter which can only be determined by deliberate study; one cannot "just naturally" pick it up, and if left to his own devices the clerk will usually adopt a clumsy arrangement. Many managers, though observing this, hesitate to suggest a change, on the assumption that a person will work better with his own arrangement than with any other, which is of course an unfounded idea.

¹ GILBRETH, FRANK B. "Applied Motion Study," p 42, Sturgis & Walton Co., New York, 1917.

3. The best motions constitute the next step, and they can only be found by the most careful analysis of the work to be accomplished, the nature of the motion required, the element of fatigue, and so forth. Occasionally a worker will, of his own accord, develop a superior way of performing a certain motion, but rarely indeed does one worker develop all of the best motions in an operation. A study of the various methods used at present by different workers will be found suggestive, but ordinarily the observer will be compelled to use his own ingenuity.

4. The next step to be taught is the correct sequence of the motions at a standard rate of speed. Gilbreth has shown that fast motions are different from slow ones, and if one is definitely to learn the right motions, he must at the same time learn to perform them at a standard rate of speed.

5. While the fourth step is being learned, the habit of speed must be developed. For it is strictly a habit. Some people acquire it more readily than others, but all must learn it.

6. Accuracy must also accompany the last two steps, but its final development may be completed after the habit of performing the right motions in the right sequence, and at a standard rate of speed, has been acquired. The worker must be taught the points at which accuracy is of the greatest importance, and also where extreme accuracy is not required. The meticulous clerk is often more of a liability than an asset.

That there are great possibilities in the development of standard methods in office work, may be realized when it is known that even in the simplest operations there is a right, as well as a wrong way, and that the difference between the two may be startlingly realized in the difference of output under each method. Thus, the clerk without training, will rarely be able to affix stamps on envelopes at the rate of more than 1,000 an hour, which works out at about 16 a minute. The standard rate of speed with the standard method is 84 a minute or 5,040 an hour. If one were simultaneously to observe two workers with these different methods, the slower one would appear to be doing the greater amount of work. A look at the output would, however, show at once that this was an illusion.

Trained and Untrained Workers. A trained clerk making entries on cards will easily make two or three entries, to each one that an untrained worker makes.

An untrained file clerk will find difficulty in filing 100 letters a day, while a trained one—on certain kinds of material—will file 100 an hour.

In the operation of any machine such as a typewriter, card punching or calculating machine, the importance of training is easily recognized and an attempt is made to employ persons only who have had such training, but since the organization knows nothing of the possibilities, it is compelled to accept the word of the clerk that he is trained. The commercial schools turn out a typist who is able to write from 30 to 50 words a minute—50 to 60 words is considered excellent—yet the typewriter companies take specially selected typists and develop many of them to a speed of 100 words a minute. Now contrast these figures with the average speed of the operators in a large majority of offices—15 words a minute!

Such training as I have been describing can never be approached in a vestibule school, which, with a limited number of teachers, must attempt to cover the wide variety of operations to be found in any office. Training

such as I have described, must be organized, and the organization must be as wide as the office itself.

The size of the office will determine who shall do the training work. In the small office, the supervisor himself will be the trainer; in the office somewhat larger, the departmental supervisor may handle the work, and in some large departments, or on some special operations, the trainer may be one of the working clerks, who is a regular clerk at all times when there are no new clerks to be trained.

Elements in Training for a Simple Operation. Elsewhere I have outlined the training for a simple operation, such as typing envelopes, a description which will bear repeating here:

"Let us suppose for example, that the job to be learned is the simple one of addressing envelopes on the typewriter. What are the elements of this work?

1. There is the placing of the copy in the most advantageous position. If a copyholder is provided, the instructor's duty is to see that it is used in the standard way, the one best way found by a scientific analysis. There is, as a rule, a tendency on the part of clerks—common also to all other workers—to depart from the best ways, and this tendency must be overcome by constant watching.

2. The layout of the work is of equal importance. 'Any old way' is not permissible. The one best way *must* be used, for unless it is, the best results will not be obtained. The instructor will not merely repeatedly tell the worker how to do it, but will demonstrate it manually again and over again, and keep constant watch until the method has become habitual and fixed.

3. The correct motions for putting an envelope in the machine, for reading and writing copy, for taking the envelope out of the machine and laying it aside constitute a cycle of operations which must be performed in the standard way each time, if the best results are to be obtained, and it must not be assumed that the worker can and will do this of his own accord. The habit must be formed.

4. Learning to read the copy the best way is important. If this is left to a random choice of method, it will be found that some clerks will write much less rapidly than others, and this will not be due to lack of finger speed but to slowness of mental reaction. The novice will usually look at the copy to read the initials, then type them, next look at the name and type that, then the street address, and finally the town and state. This may be detected by observing the manner in which the typing is done and listening to the tapping of the keys. The correct way is to read the whole in advance of the writing, and to type steadily until the entire name and address is written. This method—because of the shortness of the time required to read and commit the name and address to memory—enables the operator using it to write nearly twice as many envelopes with the same typing speed as the person using the incorrect methods.

In the process of thus visualizing the entire name and address, a decision is actually made, and the making of such decisions is, by the way, a most important element in the speed of all operations performed in the office. It is evident that in all occupations where the unit operation is small, such as the addressing of envelopes, filing of letters or cards, making entries of various sorts, and so on, every action nevertheless requires coordination of body and brain, the latter deciding, the former acting in agreement with the decision. Office operations as a rule, first require reading, second, deciding the course

to be taken, and third, taking that course, the second element not being entirely dependent upon experience, though that usually enters in large part into the process. It is also dependent upon the quick reaction of the mind, and the attainment of this quality is largely a matter of habit that has become fixed. The habit of speed in mental reaction, or what I call speed in making a decision, can be cultivated in most persons, though not in all. If the work of the slow-moving clerk is analyzed, it will be found that the chief reason of the slowness lies in this element of decision—it requires an appreciable time for him to decide to make the motion. Some clerks will hesitate before each motion, while others will move rapidly, though quietly, and seem to be exerting no great apparent effort. In typing, this has been alluded to as rhythm—in which lies the secret of speed—but it has as yet not been defined in other clerical work. Watch a slow file clerk sorting letters alphabetically; she picks up the letter, looks at it absently, then realizes that she is not supposed to read it but to find the name—which she then does; next she turns her glance on the guides in the sorter, looks at them absently, slowly finds the correct one, glances hesitantly at the letter again and puts it in its proper place. The rapid sorter picks up the letter, glances quickly, but with certitude, at the place where the name should be, finds it and at the same moment identifies the proper guide, and without the slightest hesitation puts the letter in its place. The actual motions of both will appear to be essentially the same, but one will require twice the length of time the other does, this being due altogether to the series of hesitations running through the operation.

5. The habit of speed must be developed. While the element of decision is the greatest factor in the development of speed, in addition there is the habit of making quick motions. Assuming that the worker has learned the correct ones and their proper sequence, the next requirement is the development of speed in making them. This being entirely a matter of habit, can only be taught by repeated practice and continual urging on the part of the coach.

This is the sort of instruction—on the actual method of performing the work—that is usually absent in office work, but which has been highly developed by some companies, and with marvelous results.

This job instruction need not be carried on indefinitely, for there should be a definite goal. Usually this is fixed as two-thirds of the standard rate of production, and when this rate is attained, the intensive instruction may cease, though it is good practice to continue general supervision—an occasional checking up of the work—still further. The full standard will ultimately be attained, the habit of making it become fixed, and the checking up diminished to some extent, though general supervision of course must not be entirely abandoned.

The difference between the average worker in any occupation, and the expert, is almost entirely a matter of training, yet the difference in their output is enormous, but despite this fact there are many offices which do not have any definite, organized system of training, and plead in extenuation, that it costs too much. The large and successful companies, however, do not look upon the matter in this light, and this is probably one of the many reasons why they are large and successful."¹

Importance of Standards. It cannot and must not be assumed that one can begin training offhand in an office where there has been no preliminary

¹ILL, W. H., "Office Management; Principles and Practice," p. 719 *et seq.*, McGraw-Hill Book Company, Inc., New York, 1925.

study and analysis of methods, for in the absence of this, the training work would, at most, crystallize and perpetuate the conditions then existing, or in other words, it would accomplish nothing in the way of betterment. As Henry L. Gantt once said, "The usual methods are usually wrong," but great economies can be accomplished by the office manager who first makes the wrong methods right. When this is done, training of the type I have here been describing, will not only make still greater economies, but will also improve the service and greatly reduce the burden of the office supervisor.

PREPARATION AND USE OF ORGANIZATION CHARTS AND MANUALS OF PROCEDURE

BY ELSIE LOUISE BAECHTOLD, *Editor of Manuals, Irving Trust Company*

Banking Is Similar to Other Business. Although bankers sometimes say "Our business is different," banking is not essentially different from other business. Banks manufacture, they sell, they carry on the operation of the work just as other business does. They manufacture deposits into loans and sell foreign exchange, investment, and trust services. Banks are joining with other industries in searching for the best way to go about their business; the best way to develop people; the best way to improve conditions in the business.

After several years experimentation the Irving Trust Company has decided that one important means of making progress along all of these lines is through the preparation, installation and use of organization charts and manuals of procedure. These are not magic "cure-alls"; they do not take the place of well-understood and time-tested methods of management. They are, however, important aids to management in accomplishing results along the lines indicated. In more concrete words, manuals of procedure and organization charts can be of great assistance in helping the entire staff in

1. Comprehending the task to be done.
2. Actually performing the task.
3. Aiding the making and carrying out of suggestions.

Why Charts and Manuals Are Used. In the Irving Trust Company several banks have come in through consolidations. Naturally, each of these had its own methods of operating; each was as individual as the people who made up its staff. In order to bring about similarity of organization and harmonious operation study was given to the development of a practical plan which would enable the company to function with greater ease and simplicity and in a manner which could be understood by all. A simple form of organization was adopted; all activities were classified by functions; and the territory served by offices was arranged geographically. A program was developed for the preparation of organization charts and manuals of the company's procedure, and methods for their constant revision. The program had two distinct parts:

1. Making a comprehensive plan for the preparation of charts and manuals, and a program for their continual revision.

2. Having members of the company's executive and clerical staff, as coauthors, actually carry out the various phases of the plan and program.

The Value of the Process of Preparing Charts and Manuals. That the process of preparing the charts and manuals has been valuable to the company has been demonstrated by the gain in knowledge and comprehension of the company policy, purpose and procedure on the part of all the employees. The preparation has been a means to an end. For though the manuals and charts are exceedingly useful, they are, in a sense, only the symbols of a process which is gathering momentum as it goes along and which is never ending, never complete. It will never end or be complete so long as the company continues to grow progressively. Experience is proving that the process is as important as the product.

Procedure Is Simplified by Use of Charts and Manuals. In carrying out this program the work has been simplified, many unnecessary forms have been eliminated, and better ways of doing things have been found.

It has meant improved operating conditions in the company, and most important of all, it has meant the discovery of numerous individuals in the company with fine qualities and splendid potentialities. These individuals might not have manifested themselves so soon, if the opportunity to take an active part in this program had not been given to them.

The work of carrying out this program has been correlated by a committee of five, designated as the "general guiding methods committee," the secretary of which serves as the editor of all the manuals.

Preparation and Use of Organization Charts and Manuals of Procedure. As a start in the development of the manuals program a description of the activities of every department in every office of the company was prepared. This was accomplished by having every department head and his assistants write a short description of just what they did in their department and state who did the work. In addition, each department head prepared an outline chart of his department and its sections, showing the relation between them. The material on each department was reviewed and passed upon by the officers in immediate charge of the activity. These descriptions and charts portrayed the work in the company exactly as it was. Two especially important results grew out of having employees prepare the descriptions of their work:

1. They learned something about charting and the preparation (in writing) of methods of procedure.
2. Data were provided for an analysis of the entire company.

A careful analysis of the material was made in order to see just what every office of the company was doing. Following this study, a simple type of organization was adopted.

Activities of the Company Are Arranged by Functions, and Offices by Geography. The functional type of organization has much to do with the manner in which the process mentioned previously has developed. The organization may be described as follows:

The company is made up of thirty offices—twenty-nine banking offices, for customers, and a General Office. The activities of all offices are arranged alike

into seven functional divisions—Deposit, Credit-Loan, Foreign Exchange, Investment Service, Corporate and Personal Trust, Business Extension, Interior Service. Into each group have been gathered all of the activities which should logically be together, arranged by department, then by section, then by unit. The seven divisions are arranged in three major groups—production, sales, interior service (an instrument of general administration)—just as the activities of any business can be arranged. The banking offices serve the customers of the company. The general office serves the banking offices and has no direct contact with customers. Though all offices are arranged alike in divisions, the activities of the general office are divided into three classifications—cooperative, coordinating, and proprietary.

1. By cooperative is meant assisting the offices in doing that part of their work which can best be done in one place instead of thirty, such as clearing checks, purchasing equipment and supplies, employing people, etc.

2. By coordinating is meant aiding the continuous development of better management methods for the entire company, by the study of performance reports and records of offices, the preparation of manuals of procedure and policies, the carrying on of research.

3. By proprietary is meant attending to those matters relating to ownership responsibilities, such as the keeping of records of the Board of Directors, stockholders' lists, investing stockholders' funds, etc.

The Start and Follow-up of Manuals. In this arrangement of the company the coordinators, all of whom are staff officers, play an essential part. They act as the keystone of the plan. Every divisional activity of the company has a coordinating officer with as many assistants as are necessary. The coordinators act as staff assistants to the president in reviewing and developing each of the seven divisional functions of the offices. To the coordinators are referred all questions of policy and procedure. Through them the guiding methods committee obtains the material for the manuals of procedure. They also pass upon, approve and issue to the offices the manuals of procedure covering their respective activities.

A Comprehensive Plan of Publications of All Activities. The plan, which is being followed in the development of the process, has been mentioned. There are eight steps in it. The first five, having to do with manuals of procedure and other informational literature about the company, are of particular concern to this paper and include the preparation of:

1. **Handbook of Information for Staff.** A small booklet given to every new employee. It states, briefly, the facts relating to the organization of the company, some general instructions, and an outline history of the company.

2. **Office Information and Directions for Staff.** A small booklet giving pertinent information about relations of employees to the company, customers, fellow employees, and certain instructions about the office in which employee is at work. All employees of an office receive copies.

3. **Summary of Activities.** A short story of the work done throughout the company, telling what and where it is but not how it is done. For all members of the company.

4. **Manuals of Procedure for All Divisions.** Books describing in detail the operation of the activities in the company—one (or more) for each func-

tional division. For the use of those concerned in a particular activity as reference and instruction books, or for any in the company desiring to become informed on the subject.

5. *Manuals of Official Policies for All Divisions.* Limited series of books setting forth the company's policy in regard to its activities. These are for confidential use of the officers concerned.

The foregoing sketch has been given in order that the background of the plan for and process of the preparation, use, and development of charts and manuals in the Irving Trust Company may be understood by readers of this paper.

The Process of Preparing the Manuals. Preliminary drafts of manuals of every department were made first. When the manuals program was begun each coordinator was asked to furnish to the general guiding methods committee detailed information about the work of every department in his activity. It was suggested that those actually engaged in the various activities in the offices might be the best ones to prepare the information. So each coordinator discussed with the department heads what was wanted and requested them to have members of their staffs prepare the desired material.

Many of those who took part in this work had never attempted to put into writing their knowledge of the work they were doing. Naturally, it has taken much time and thought and encouraging to get the material together this way. If the committee or some one person had prepared the information and had given it to those in the activities described to use, there probably would have been little interest displayed in it and practically no discussion of it. But when those doing the work wrote down their own descriptions, they found much to discuss, much to check up, and they began to question some of their own methods in handling their work. Those who write, also learn, and by learning, improve themselves and help to improve the methods which they use.

The coordinators receive the material from the departments and review it carefully. It sometimes needs much working over in order to have it describe the work as desired. When a coordinator feels that the manual which he is reviewing has been sufficiently completed, he sends it on to the editor to organize into the approved arrangement. The material as prepared in the departments is usually in narrative form. (No request for any particular arrangement of the material was made in the beginning because it seemed better not to have too many directions for those preparing the data. Facts about the work were the essentials.)

Editing the Material. As the information is prepared by a number of people, it reaches the editor with many types of phraseology and in a variety of forms. The editor goes over the material carefully and prepares an outline of the major points. This outline is similar to one made for a speech or a debate. When it is completed, the details of the points covered are built into the frame work, and note is made of irregularities found in the text submitted. This simple form of outline sometimes brings out many irregularities, such as incompleteness of description or illogical sequence of operation. To the revised text are added summary pages and charts of the activities and pertinent illustrations of actual operations, machines, forms, and processes.

The material in this new form is then returned to the coordinator for further review. Sometimes the material passes back and forth a number of times between coordinator and editor before final approval. When it is finally approved, a copy is forwarded to the president, who reviews all of the manuals. Upon the president's approval the manuals are prepared for the printer.

In the twenty-five to thirty departments of the seven functional activities of the company there are from fifty to several hundred persons who have something to do with the preparation of the material. All material is correlated, however, by the same editor for the obvious purpose of securing uniformity of style and arrangement.

The First and Second Editions. The early books of the first edition were set up in a simple inexpensive fashion as it was planned to replace them promptly by a second, more comprehensive edition. Zincograph, a photographic reproducing method, is used for the text, and flexible loose-leaf covers for binding. Recently, substantial, more permanent covers have been used, and similar ones are being planned for the second edition, now in process. It is expected in the second edition to have the books so arranged that they may be kept perpetually up-to-date without the necessity of rewriting the entire volume. In preparing this edition the comments and criticisms on the first edition, as received from the officers and members of the staff, are carefully reviewed. As a result, the second edition represents a composite of all of the best practices being followed in all of the offices, and will aid in establishing more uniform procedure throughout the company.

The Number of Copies Issued. Enough copies of a manual are printed to provide every officer in the company, and every member of the staff in the activity concerned with a desk copy. Additional copies for the company library, other members of the staff, and for reserve are printed. This means that for each activity there are prepared from 300 to 1,000 copies.

Distribution and Check-up Plan. This plan makes sure that every person who is entitled to a copy of a manual will receive one and will review it. When the manuals are received from the printer, the coordinators have the responsibility of distributing them. The plan of distribution so far followed has consisted of three parts:

First, a letter from the president is prepared to accompany manuals sent to all officers. This letter states briefly the reasons for the manuals and asks each officer to review his copy and send to the president, by a certain date, any comments which he may have to make on the work. Letters and manuals are sent to all officers simultaneously.

Second, after the officers have reviewed the manuals, copies are sent to every member of the activity in every office with a letter, and a review form for the recipient to fill out and return. This form contains four questions:

1. What are the differences between the methods you use and the methods described in the manual? State variations.
2. What operations carried on in your department are omitted from the manuals? Describe fully.
3. What operations described in the manual are omitted in your department? State page and subject heading.

4. What methods used in your department are, in your opinion, better than those described in the manual? Outline your methods in detail and give reasons for your opinion.

After every person working in the activity in every office of the company has thus had an opportunity to answer these questions, the result is a rather comprehensive report on the possible variations in the practices as followed in the different offices; and a valuable collection of data to use for the second edition of each manual.

Third, all of the reports from the staff members are carefully checked by the coordinator or his assistant, and helpful suggestions and criticisms are incorporated into the second edition.

Continual Research for Improvement of Methods. One of the regular duties of the coordinator of each function is the study of methods and the search for newer, better ones. This procedure is necessary in order to maintain steady effectiveness in the company's methods. As better methods develop, the manuals serve as a means for putting the improved methods into actual practice.

Results of This Method of Preparation. Having the people doing the work prepare their own directions has brought about some interesting results. Among them, several are worthy of especial note:

1. Employees take pride in the fact that they have had a part in the preparation and development of the manuals.
2. Employees gain a broader viewpoint regarding all of the company's activities.
3. Above all, this method of preparation provides a means
 - a. Continuously to follow up and revise methods.
 - b. To keep all members of the company advised periodically of changes in methods.
 - c. To afford every one in the company a ready opportunity to submit suggestions regarding procedure.
 This helps to solve a problem frequently baffling in large corporations.

The Manuals Are Used in Various Ways. The first edition of the manuals is being used primarily as a means of checking up all procedures in all departments in all offices of the company. The instructions in the manuals represent the best way of carrying on an activity at the time the information is written. But they are all subject to change, of course, and this is understood by those using the books.

The manuals are also being used as reference books when questions regarding correct procedure arise. This use takes into consideration, always, the fact that the books are not "standard practice" for all time, but are being constantly brought up to date. A third use being made of the manuals is as guides in instructing new members of the various activities. In this they are proving extremely helpful.

Summary. Thus the Irving, when the program is completed, will have a collection of material in the

Seven detailed manuals of procedure,
Seven detailed manuals of official policies,

One summary of activities,
One handbook of information,
One office information and directions booklet,

which is being developed continuously, with the aid of the staff, to be used for these principal purposes:

1. To provide an organized, classified, written description of what should be done and how it should be done, in each and every activity of the company.
2. To enable all present and future employees readily and quickly to become familiar with the general purposes and policies of the company, and their own work in particular.
3. To provide a basis for comparing the actual performance, in any given activity, with written standard practice.

THE HEALTH OF OFFICE WORKERS

BY LEVERETT D. BRISTOL, M.D. Dr. P.H., *Health Director, American Telephone and Telegraph Company*

The Health Status and the Needs of Office Workers. The Office Worker as an Individual

a. Sickness and Sex. Without attaching undue significance to the commonly observed fact, it should be mentioned in passing that other things being equal, there is for the public in general a greater prevalence of sickness among women than among men. Moreover, according to a study carried on over a period of years by the United States Public Health Service of about thirty-five industrial sick-benefit associations, it was brought out that of their cases of disability lasting longer than one week, female members were disabled from sickness more often than males to the extent of 50 per cent in the period 1921-27. The higher rate was not attributable primarily to conditions of the puerperal state nor to diseases of the female genital organs, because most of the reporting associations pay benefits only for ailments common to both sexes.

Consideration also must be given to the fact that the nature as well as the amount of illness differs according to sex. For example, evidence is available which indicates that in the general population, young women during the age period from fifteen to twenty-five show a much higher rate for tuberculosis than do young men. In the study referred to above, comparing the nature of illness according to sex, one finds that "the frequency of eight days or longer cases among women was more than twice that of the male rate for diseases of the nervous system, diseases of the pharynx and tonsils, appendicitis, the genito-urinary group, exclusive of nephritis, the general disease group, and for ill-defined and unknown causes." However, among women the rates for hernia, pneumonia, rheumatism, diseases of the veins, bones, joints, and organs of locomotion were considerably less than among the men.

b. Sickness and Age. In any analysis of the sickness experience of an industrial group such as office workers, or in the planning of a health program,

the facts regarding the distribution of employees by age also are of interest.

From such observation as I have been able to make among office workers with over two years' term of service, frequency rates of sickness over seven days' duration are fairly constant between the ages of twenty and fifty; before twenty the rates being less and after fifty higher, the latter rates being proportionately higher for women than for men.

c. Sickness and Term of Service. Various industrial morbidity studies would seem to indicate, at least when short-term illness is included, that the frequency tends to be lower in every age group among employees of five or more years' service than among those who had been working less than five years. Frequency of sickness cases over seven days' duration, of office employees with over two years term of service, does not show any significant difference from the standpoint of increasing term of service.

d. Sickness and Marital Condition. Such information as is obtainable on the question of sickness of married women in industry, indicates that as a class, women who are working and maintaining homes for their husbands, show a slightly poorer record of sickness disability than single women. The most striking contrasts between the two groups are likely to be found in the common respiratory illnesses and disorders of the nervous and digestive systems. It is unfair, however, to generalize on the strength of such comparisons, because industry is full of married women who adjust their home affairs and business careers so efficiently that their health is certainly as good as and oftentimes better than that of the unmarried girl who is more inclined to tax her bodily endurance with various forms of amusement and pleasure. The sickness experience of married women in office positions will be found to be influenced by the natural consequences and accompaniments of marriage, and by the poor records of a relatively small number of women whose double burden of work is too heavy.

e. Causes of Sickness. While births and deaths in most communities are now accurately reported and recorded, according to the requirements of law, the vast majority of cases of public illness in a community are not required to be reported. Only about five per cent of all cases of illness, chiefly those of a communicable nature, are made reportable by law. In other words, in ninety-five per cent of the cases of sickness there is very scant and incomplete knowledge as to their absolute and relative prevalence. For this reason it has been practically impossible in the past to compare the sickness of industrial groups, from the standpoint of "causes," with any known public standards.

A recent twelve months' morbidity survey of sickness in rural New York State, including a total estimated population of 100,000 out of which there were 98,069 recorded cases of sickness, is at least of interest in this connection as showing the distribution according to causes of the non-reportable, as well as reportable diseases in a cross-section of the public. In this study of public sickness it was found that the leading cause was colds, including influenza, with 28.3 per cent of all cases. Digestive disorders were responsible for 14.6 per cent followed by operative and traumatic surgical cases (except gynecologic), 13.7 per cent; 56.6 per cent of all cases of sickness were listed under the above three heads. Following these, of the more important causes

neuroses (or all types of sickness based on a functional disturbance of the nervous system) comprised 7.8 per cent and tonsillitis 6.2 per cent. The survey also showed "that the diseases responsible for the bulk of mortality play a comparatively inconspicuous role among the causes of prevailing ill health."

In general, industrial experience would seem to indicate that respiratory cases constitute by far the largest class of illness and are responsible for most of the fluctuations in the disability rate from month to month and year to year.

f. Causes of Death. While pulmonary tuberculosis as a cause of death now ranks for the public in general below heart disease, pneumonia, and even cancer in many communities, tuberculosis of the lungs is still considerably in the lead as a cause of death in this group of office workers, more so for females than for males. Heart disease, influenza, pneumonia, and kidney disease follow in order of frequency. These facts probably reflect chiefly the young age group rather than a particularly hazardous occupation.

The Environment of Office Workers

a. Sickness and Size of Community. Among the public in general it has been said that apparently, the larger the community the higher the sickness rate, and vice versa. In the morbidity survey of rural New York State, mentioned above, there were nine hundred and ninety-four cases of illness reported per physician in the larger incorporated villages and six hundred and forty-eight cases per physician in the small towns and unincorporated territory. It must be granted, however, that such figures may not be entirely trustworthy and significant as an indication of more sickness in cities and towns, as compared with rural districts. It may be in the country a question of the lack of availability, the greater distance and the higher average cost of medical visits and care. According to a recent study, "the average farm family in the United States is 7.03 miles from the nearest doctor, and the charge for a call to the home of the average farm family is \$7.63." As compared with the city resident, the farmer depends on "home remedies" and calls the doctor as a last resort. If a true census could be taken it probably would be shown that such a practice leads to more sickness in the country than otherwise would be the case.

b. Effect on Health of the Number of Workers in Office or Building. While no reliable data are at hand which would indicate conclusively the effect on health of the number of workers in an office or building, the general opinion is that the larger the office or building, the more opportunity there is for the spread of so-called "crowd" or "spray-borne" diseases through discharges from the upper respiratory tract. Overcrowding is a distinct menace to health. It must always be borne in mind, however, that a small office or building may be, and frequently is, more crowded than an office or building of larger size. Apparently the linear distance between workers in an office is even of more importance from a health standpoint than the number of cubic feet of air space per person. The closer the contact, the greater is the opportunity for the transmission of infection.

c. Advantages and Disadvantages of an Office Environment. In a sense, office workers lead a somewhat "protected" life from a physical standpoint. They are not so subject to the extremes of weather conditions as are the

outdoor workers, and they escape to a certain extent the hazards of various other indoor industrial pursuits involving accidents, dust, and various chemicals, gases, and fumes.

On the other hand, they have not the benefits of so much fresh air, sunlight and exercise as outdoor workers, and their work tends to be of a sedentary, monotonous nature, often leading to various mental as well as physical ills. The more they are crowded together, the more they suffer from crowd diseases. Moreover, in any consideration of this group from a health standpoint, the fact that individuals of subnormal physical condition and endurance tend to gravitate toward indoor office work, must be taken into consideration.

The features of an office environment which are of particular importance from a health viewpoint are lighting, heating and ventilation, and seating. There are other factors such as wages, hours of work, rest pauses, sanitary toilet facilities, recreational opportunities, and adequate provision (at least in large offices and industries) for wholesome lunches, which have a definite relation to the health, efficiency, and morale of office workers. Most of these features, however, are of approximately equal value to all workers in industry and need not be discussed at this time. There are one or two of these environmental factors which it might be well to emphasize particularly for office workers.

d. Ventilation, Heating, and Lighting. The problems of ventilation, heating, and lighting are intimately associated with climatic and weather conditions. One of the more recent findings, with reference to the bearing of climate and weather on health, is that much of the illness due to diseases of the upper respiratory tract prevailing in the winter and spring is associated more with the amount and periods of precipitation (rain and snow) than with low temperature. Apparently chilling of the body, due to rapid evaporation of body heat caused by wet clothing, shoes, and stockings, has an influence of importance in the causation of colds and other common diseases of the nose, throat, and lungs.

One of the most serious health problems of the average office is that of ventilation. The fundamental requirements for good ventilation are: proper temperature (68 to 70°F. for average office-working conditions), a moderate relative humidity and sufficient but not too great movement of the air. The thermometer is still the chief guide to good ventilation and should be found in all offices. Better than depending on a single thermometer at one point in a room, it is desirable to have two or three instruments at different points. It should be the practice to note temperature readings at regular intervals on an office record, and to take the necessary steps to control the same as need arises.

As a rule, fairly satisfactory facilities and conditions exist in offices from the standpoint of heating. There is a tendency to overheat, rather than to underheat. In this connection the problem of the difference in weight and styles of dress of women office workers must be taken into consideration, and possibly more definitely supervised and controlled. Side by side in the same office often may be noted three or four different types and weights of dress, largely dictated by style and the personal whims and habits of the individual. One clerk may be wearing a short-sleeved dress of very light weight material;

next to her may be a girl with a heavier dress and long sleeves; adjacent to her may be one with not only a fairly heavy dress, but in addition, a smock (or what amounts to a light overcoat) over it, and still another may be wearing in addition to a dress a rather heavy sweater! It is, of course, difficult under these conditions to furnish a temperature, humidity, and movement of the air satisfactory to all individuals.

In southern states, and during the hot summer months in all offices, the problem of adequate cooling may be most acute. The use of fans, some of which should be placed along the floor, keeps the air in more rapid motion and facilitates the evaporation of heat from the bodies of the workers, thus making them more comfortable.

In some cases it may be necessary to give careful consideration to various methods for conditioning the air of offices, not only in the interest of satisfactory service, but in the interest of the health and welfare of those employees who have to work in these rooms. It may be that we shall have to revise our ideas about "the best room temperature" and "the best relative humidity" for office employees. Certainly there is no relative humidity that may be designated as "normal" or "average" because it depends so much on other factors; and even the sanitary gospel of "68° F. room temperature" may have to be revised to meet the needs of modern styles and habits in clothing. There is already a significant tendency to consider a so-called "effective temperature scale" which attempts to measure the effects of dry bulb and wet bulb temperatures and velocity of air, including a "zone of comfort," instead of depending on the single dry bulb reading.

Lighting of offices may range all the way from the bright, natural sunlight of outside offices to the rather subdued and often dim light of inside rooms. The fact must be borne in mind that disease germs grow and reproduce more rapidly in rooms from which sunlight is absent. Sunlight is one of the most efficient germicides, while at the same time it serves to enrich and vitalize the blood and tissues of the human body.

Recent investigations tend to demonstrate that ordinary window glass transmits very little of the health giving ultra-violet rays of sunlight. Experiments are being carried on by different industries to determine the possible value and practicability of the substitution of specially manufactured glass, which is said to transmit a considerable amount of ultra-violet light, for the ordinary window glass now in use. In this connection it should be observed that no matter what the type of glass may be, in many of our large cities, little or no ultra-violet rays reach the window on account of smoke, dust, fog, etc. Any cooperation or assistance which those interested in business management may render to public health authorities in their campaigns for the abatement of the smoke nuisance is in the interest of the health of such groups as office workers.

e. Special Working Conditions. Even in the same office, the health problems of individuals may differ according to their special duties and responsibilities. Machine workers, including stenographers, typists, and comptometer operators are more subject to posture and monotony fatigue than are clerical workers. Likewise routine, supervisory, and executive office

workers may differ in their reaction to monotony—with the routine worker more prone to fatigue.

The chief health problem of the executive, who is usually of the older age group as compared with the younger routine worker, is that of the insidious so-called "degenerative" diseases which have their onset or become evident with advancing years. Cancer, heart disease, kidney disease, and such associated conditions as arteriosclerosis and hypertension must be considered more vital problems of the office worker than colds, influenza, digestive and nervous disorders, from the standpoint of the executive of advancing years and term of service.

Suggestions for Dealing with the Health Problems of Office Workers
Essentials of an Industrial Health Program. Industrial hygiene has come to occupy a leading place in the field of public health. In reaching its objectives the following measures are considered essential by leading authorities: (1) selection of applicants and their assignment to suitable employment; (2) assistance to employees in their own health maintenance and in recovery from disease or accident; (3) sanitary supervision of working environment and social assistance in home and community problems; (4) research to improve methods and results and to extend the knowledge of industrial health. It is to be assumed that all of the above essentials, so far as is practicable, should be incorporated in a coordinated health program for office workers.

Characteristics of the Office Worker Group. In dealing with the health problems and needs of office workers, an adequate program must take into consideration the facts that the great percentage of such individuals (1) live in cities; (2) work in fairly large groups; (3) are of the younger ages; (4) are single and of the female sex. Moreover, the office worker is on duty approximately eight hours a day. What of the other sixteen hours? There is a very close relation between community and home life and office work that cannot and should not be forgotten. Any comprehensive program for the health of office workers must reach back from the office into the community and home, and concern itself with the individual habits and modes of life. This requires tact and friendly cooperation, but should not lead to paternalism.

Importance of Personal Hygiene. Modern public health practice in the last fifty years has progressed from its strictly "environmental" state, when the questions of sanitation and environment were of paramount importance to the newer era which concerns itself chiefly with the individual human "machine." In other words, health practice, even in industry, has become largely a question of personal hygiene.

As has been the case in the evolution of so many of our human accomplishments, the more simple health problems have been solved first, leaving the more complex for later consideration. The accomplishments of the so-called "era of sanitation" naturally preceded those of the present "era of personal hygiene" largely because the problems involved were more simple. It is easier to control our environment than it is to control ourselves. It is vastly more simple to chlorinate a public water supply or to pasteurize a milk supply to protect the health of millions of people, than to control one individual's conduct and to make him live properly and follow the reasonable rules

of health. For this reason, it has been much easier to eradicate such diseases as yellow fever, typhoid fever, hookworm, and malaria, than to control tuberculosis, syphilis, gonorrhoea, heart disease, cancer, influenza, or the common cold. The slogans of the older era were "control" and "legislation." The key word of the modern health movement is "education." The latter may be slower, but is surer.

Preemployment Physical Examinations. The tendency in industry to use more care in the selection of applicants through preemployment physical examinations should, of course, apply as much to office workers as to others in the industrial group.

According to the general opinion of authorities in this field, "the physical examination may be called the keystone of industrial health work." The chief objects and advantages of physical examinations, as summarized by the National Safety Council, are:

a. Objects.

1. To place the worker in the occupation which suits him best.
2. To detect the presence of remediable physical defects in order to enable the worker to correct them.
3. To determine the presence or absence of serious organic disease, either of which may have an important bearing on employment selection.
4. To prevent occupational disease, by excluding susceptible workers from specific hazards.
5. To prevent the spread of communicable disease by the exclusion of infected persons.

b. Advantages.

1. Presents a favorable opportunity for health education.
2. Enables the early discovery of disease.
3. Makes possible the proper placement of the worker.
4. Helps to prevent or lessen the effects of epidemics.
5. Tends to reduce absenteeism, when used as a part of a health service.
6. Is a factor in lessening accident occurrence.
7. Reduces the possibility of unjust claims for injuries.
8. May increase efficiency and production through proper placements.
9. Provides a means for economic control of future medical expense.

The council states:

Protection for the worker, the fellow workers and the industry are the chief motives which should actuate the inauguration of this important industrial health measure. Physical examinations should never be made solely with the idea of weeding out the unfit.

It is suggested that the greatest needs in the further extension of physical examinations of applicants for employment are: (1) the development of standardized methods based on suitable standards of classification and acceptance; (2) the adoption of a minimum standard form or record card for use in such examinations; (3) adequate follow up to insure the highest possible number of corrections of defects and abnormal conditions found.

It probably would be unwise at this time to attempt to require, for office workers as a whole, routine medical examinations of all applicants for employment. This is a matter which of necessity must largely be decided by

management on the basis of local conditions, needs and facilities. Such examinations by experts, preferably medical, should be constantly encouraged and adopted as rapidly as is possible and feasible.

Management's Opportunities and Responsibilities for the Health of Office Workers. After a worker has been accepted for employment, management has certain opportunities and responsibilities for the health of the employee, including: (1) healthful working conditions and environment; (2) facilities for health education and supervision; (3) diagnostic facilities and aids; (4) emergency medical and social treatment of cases of sickness and accident. The great question with all those interested in management who want to improve the condition of employees in general, including office workers, is or should be, how to get employees to try to improve themselves.

a. Working Conditions and Environment. The health needs of office workers, from the standpoint of good ventilation, proper heating and adequate lighting of offices have been mentioned. It is unnecessary to dwell on the fact that herein lies one of management's chief obligations for the health of office workers. Suitable seating facilities which will be conducive to proper posture also should be of constant interest to management. Improper posture leads to poor work and ill health.

In this enlightened age it is hardly necessary to emphasize the relation to health and efficiency of such factors as hours of work, rest pauses, luncheon periods, and general sanitary and toilet arrangements. For large offices and industries this involves among other things, the development and maintenance of rest and recreation rooms, lunch rooms and cafeterias. Not the least important provision is for sufficient, sanitary locker space for coats, hats, rubbers, and umbrellas. If precipitation in the form of rain and snow, with the opportunity for wet clothing and chilling of the body, has a direct relation to the onset of upper respiratory diseases, and if these diseases are the leading causes of sickness disability among office workers, then surely the development and maintenance, in large offices at least, of a so-called locker-room loan collection of stockings, rubbers, umbrellas, and other articles of clothing to be used by employees in cases of emergency is a measure to be encouraged by management.

b. Periodic Health Examinations. A number of the larger industrial organizations, through their medical departments, make available for office workers periodic health examinations, while others at least take steps to encourage their employees to go periodically to their family physicians for such examinations. While the value in general of these examinations to the individual is now generally recognized, their practical application from the standpoint of management and working forces must be carefully considered. To have employees examined periodically by company physicians should be secondary to the education of employees as to the value of an occasional physical check up even by their own or any well-qualified doctor. As a rule, examinations should not be required or compulsory, but considered only as a voluntary matter on the part of the individual. Moreover, all results of such examinations should be kept strictly confidential between the employee and the examining physician. If the original applicant examination is of value in helping to make the person fit for the job, the periodic examina-

tion of employees is of value in making them fit to continue indefinitely in their jobs with satisfaction and contentment. In other words, even so valuable an instrument as the periodic health examination is of little ultimate worth if not intelligently followed up by attention to and correction of defects or abnormal conditions brought to light by these physical inventories.

In the development of any plan for periodic health examinations of office workers, special emphasis should be placed first on the examination of executive and supervisory forces, of older age groups, and of those who are known or suspected to have impairments.

c. Health Supervision. Physical examination of applicants for employment and periodic health examinations of employees, considered above, are inspection measures which are of value only in so far as they are followed up by and related to a continuous and well organized program of health supervision.

By health supervision in industry is meant a fixing of responsibility for the health of individual employees at least during hours of work, on the person to whom such employees report. Following are some of the suggested ways in which supervisors in large offices may be ever watchful of the health of employees working under them:

1. Keep and follow the attendance records of employees, noting absence due to incidental or short-term illness, as well as those due to longer disability.

2. Carefully observe the appearance and attitude at work of individual employees, noting any slight departure from the normal.

3. Refer cases early and promptly to the medical department, or to their own family physician, when any evidence of incipient disease, abnormal condition, or repeated accidents are noted.

4. Observe and keep a record of all important working conditions, particularly temperature, air movement, light, posture, etc.

5. Maintain a proper supervisory relation with each individual in order to guard against any mental maladjustments and to promote mental health.

d. Health Education. In large offices and industries there should be more attention given to the development and organization of facilities for addresses, lectures, and group conferences on health subjects. Regular magazine or house-organ articles on health should be a part of every company's program; these should be supplemented periodically by special bulletins and leaflets.

Visual education on health topics should be more developed than it has been to date. Health posters should be more generally used in offices and other places of work. Motion and talking pictures and attractoscopes also should be more generally used. While health is an all-the-year-round problem, and a complete health program should be continuous throughout the year, the educational value of special campaigns should not be overlooked. As in all other lines of educational work the personal or individual method of instruction through the spoken word and demonstration is of most value. It is because of this fact that health courses for office and other employees have been so successful.

e. Medical and Social Service. A wide range of practice exists in large offices and industries so far as the organization of medical work and home visiting of sickness cases are concerned. In some instances no regular medical

unit is available, the company depending on and making use of one or more local physicians, applicants and employees going to the doctor's office for examinations and attention when necessary. In other instances practically all so-called physical examinations, hardly more than superficial inspections, are made by nurses or lay employment workers.

The majority of industries employing large numbers of office workers have medical units of their own, some of which are highly organized with medical and nursing staffs and all of the modern equipment required, while others depend on a minimum of staff and equipment. In the latter, the medical officer serves chiefly as a "contact" between the sick employee and a properly qualified physician or surgeon. Mention should be made of the value of such social and economic aids to the health of office workers, as home visiting by nurses and lay personnel workers, and the development and administration of sickness benefits.

In the larger and more highly organized industrial medical departments the following services are usually available:

1. First aid in sickness and accidents.
2. Advice on medical or surgical problems.
3. Attention to ailments of short duration and of a character not requiring absence from work.
4. Laboratory examinations, including in some instances X-ray in cooperation with employee's physician.
5. Routine physical examination for employment, or in cases of suspected disease.
6. Periodic health examinations.
7. Distribution of health literature.
8. Cooperative services with benefit committees.

Industrial medical service should not encroach upon the private practice of medicine. In the field of curative treatment industrial medicine should serve in emergencies and as an intelligent aid to and contact between employees and private physicians; it should be concerned chiefly with inspection and prevention.

*"To cure is the voice of the past,
To prevent is the divine whisper of today."*

OFFICE WORKING CONDITIONS AND EXTRA COMPENSATION PLANS

By H. J. TAYLOR, President, The Club Aluminum Co.

The Survey Covers 174,053 Office Workers. The principal purpose of this paper is to provide office managers, personnel directors and others interested, with information regarding the working conditions in a large number of representative offices. The facts presented in this paper were obtained from approximately 300 questionnaires filled in and returned by that number of concerns which are members of the American Management Association. A total of approximately 650 questionnaires were sent out and

approximately 350 were filled in and returned, giving us better than a 50 per cent return on the questionnaires.¹

There are a total of 174,053 persons employed in the offices represented in the survey. Of this number 101,220 are males and 72,833 are females. The industries represented by the concerns included in the survey are: insurance, 39; educational institutions, 26; food products distribution, 22; banks and trust companies, 19; metal manufacturing, 39; appliances manufacturing, 19; accessories manufacturing, 46; lumber companies, 8; fabric manufacturing, 11, and miscellaneous, 76—the latter including hotels, publishing houses, refining companies, public accounting, laundries, stock exchanges, radio distribution and various manufacturing industries.

Offices Grouped According to Number of Office Employees. In order to be able to compare the working conditions prevalent in the smaller offices with those in the larger offices, the concerns reporting were classified into four separate groups. Group one is composed of 62 offices which have from 1 to 50 employees, the average per office being 26. Group two is made up of 96 offices which have from 51 to 200 employees, the average per office being 119 employees. Group three is composed of 68 offices which have from 201 to 500 employees, the average per office being 331. Group four is composed of 78 offices which have more than 500 employees, the average being 1,877.

Survey Returns Classified. In submitting the results of the survey, we have classified the information under the general headings: hours of work, vacations, compensation for time off, compensation and promotion, special privileges, health and recreation, welfare and education, and general summary, in the order named.

HOURS OF WORK

Hours Per Day. The average hours of work per day, excluding Saturdays, for offices included in group one, the smallest offices, are seven hours and forty minutes. In group two the average working hours are also seven hours and forty minutes, in group three, seven hours and thirty-seven minutes and in group four seven hours and thirty-seven minutes. The results show that there is a slight decrease in the number of working hours in the large offices as compared with the small offices. Of the 304 offices reporting on this question, 39 per cent have the eight-hour working day, 53 per cent have less than eight hours to the working day, while 8 per cent have more than eight hours to the working day; the average of all the offices is seven hours and thirty-eight minutes. Seven and one-half to eight hours are the most prevalent hours of work per day excluding Saturday.

The offices reporting in group one average four hours and thirteen minutes working hours for Saturdays. Group two averages four hours, group three, four hours and four minutes; group four, three hours and fifty-five minutes, and the total of all offices reporting on this subject average four hours and three minutes. We find that the large offices, on the average, have shorter working hours than the small offices. The average of this group is eighteen minutes under group one. The total for all offices reporting shows that

¹ As of Nov. 4, 1927.

four hours of work for Saturday is the most popular; 45 per cent of all reporting have the four-hour day. Twenty-four per cent have over four hours and 31 per cent have less than four hours.

Less Hours of Work during Summer Months. Three hundred and one offices replied to the question "Have you less hours of work during summer months?" Two hundred and fifty offices, representing 83 per cent do not have fewer hours of work during summer months, while 17 per cent do have. It is quite evident that the practice of providing shorter working time during summer months is not general and cannot be considered as standard practice.

A number of concerns are closing the office on Saturdays in order to provide better opportunities for outdoor recreation over the week ends. Some of these offices find the improvement in the health of their employes, because of the outdoor recreation together with improved morale and good will, have resulted in the reduction of hours being a good investment on the part of the office. It is interesting to note that the smaller offices are not as active in providing fewer hours of work during summer months as the larger ones. Banks and trust companies appear to be the leaders in providing fewer working hours during the summer months.

LESS WORKING HOURS IN SUMMER MONTHS

Rest Periods. It is interesting to note the difference in the policies regarding rest periods in the small offices as compared with the large ones. Just 10 per cent of the offices in group one provide rest periods, while in group four, the largest offices, 38 per cent provide rest periods. The most popular length of time for a rest period seems to be from ten to twenty minutes. Of the total of 302 offices reporting, just 22 per cent provide rest periods. These results show that rest periods can hardly be called a standard working condition but it is evident that there is a gradual movement towards rest periods particularly in the larger offices. It has been found by tests in a number of these offices that greater production is obtained on the part of detail workers such as comptometer operators, typists, ediphone operators, ledger clerks etc., when rest periods are provided.

A number of the offices reporting provide two or three minutes for light physical exercises during the rest periods. While the rest period cannot be considered a standard working condition of larger offices, at the same time, especially with certain groups of detail workers, it is worthy of investigation on the part of office managers and others in charge of the administration of offices.

VACATIONS

Vacation Allowance. The answers to the question "How many days vacation is the usual allowance for the majority of your employees?" were quite uniform. Two hundred and sixty-nine of the 304 offices answering this question provide twelve working days' vacation with pay. All of the four groups were quite uniform on this policy. Of the total reporting just 6 per cent provide six days and 4 per cent provide from twelve to eighteen days' vacation. It is quite evident that twelve working days' vacation is the standard vacation allowance.

DAYS VACATION PER YEAR

provide extra time on vacations for long service. This policy is in effect more in the large offices than in the small offices. Of the total of 302 offices reporting on this question, 57 offices provide extra time for long service and 237 do not provide extra time for long service. Long service is often recognized with bonuses, service buttons, etc., but it cannot be considered a standard working condition of offices to provide extra time at vacation time for long service.

Service Necessary to Warrant Vacation. The answers to the question "How long must an employee be with you before he or she is entitled to a vacation?" show that 118 of the 301 concerns answering this question require six months' service before the employee is entitled to take a vacation. The total results show that 72 per cent of the offices reporting require six months or less while 28 per cent require over six months before the employee is entitled to take a vacation. Most offices require that vacations be taken during the summer months, usually between June 1 and Sept. 1. In a large majority of offices an employee coming with the company after June 1 is not entitled to take a vacation until the following summer. A number of concerns allow one day for each month of service during the first year's service with the company. In other words, if an employee, under this policy, came with the company on Mar. 1, he or she would receive ten days' vacation that year. The most popular policy seems to be the requirement of at least six months' service before the employee is entitled to a vacation.

Saturday Preceding Vacation Period. The answers to the question "Are employees allowed the Saturday preceding the vacation period?"

show a difference of policy between the large and small offices. In group one, composing the smaller offices, 43 per cent of the offices reporting allowed the Saturday preceding the vacation. In group two 27 per cent, in group three just 16 per cent, and in group four 23 per cent allowed the Saturday preceding the vacation period. Here we see that the small office is more lenient than the large office. Of all offices reporting, 27 per cent allow the Saturday preceding the vacation, 69 per cent do not allow it, and 4 per cent allow it sometimes. In the larger offices it is more difficult to allow the employees to take the Saturday preceding vacations, than in the smaller offices and that, no doubt, is the reason why this policy is in effect more in the smaller offices than in the larger ones. The policy of allowing the Saturday preceding the vacation can hardly be considered as a standard working condition but attention is called to the fact that in the smaller offices approximately 50 per cent allow the Saturday preceding vacations. This policy is at least worthy of investigation by individual offices but consideration of it should be on a basis of whether or not such a policy would be a good investment on the part of the office.

Extra Time for Legal Holidays. Of the offices reporting on the question "Is extra time allowed for legal holidays falling within an employee's vacation period?" 41 per cent allow extra time and 59 per cent do not. The practice of allowing extra time for legal holidays falling within an employee's vacation period is growing in favor. It has been found that employees are shunning, as much as possible, those weeks during the summer months in which there are legal holidays, such as the Fourth of July and Labor Day. This causes some difficulty in working out vacation schedules and if employees are forced to take their vacation during those weeks, they are not, in all

cases, satisfied. Some offices do not provide the extra time during the regular vacation period but give the employee an extra day off later in the year. The policy of allowing extra time for legal holidays falling within an employee's vacation period is worthy of consideration in view of the fact that over 40 per cent of the offices included in this survey now have that policy in effect.

COMPENSATION FOR TIME OFF

Absence Caused by Sickness or Accidents. The policy on payment for absence on account of sickness or accidents is quite uniform in all four groups of offices. Of the total of 300 offices reporting on this subject, 93 per cent pay for absences on account of sickness or accidents, 2 do not pay for such absences, and 6 per cent pay sometimes.

Proportion of Employee's Salary Paid. Eighty-six per cent of the offices reporting pay the regular full compensation of the employee during such absence and 6 per cent pay from 50 per cent to 75 per cent of the regular compensation. It is quite evident that it is standard practice to compensate employees for absences on account of sickness and accidents. The usual practice is to pay the full compensation of the employee during such absence up to a certain maximum number of weeks' pay. The usual maximum allowance is from two to four weeks' pay, some companies graduating the maximum according to length of service.

Service Required to Come under Plan. It is hard to reach any definite conclusion from the replies to the question, "How long must an employee be with you to come under this plan?" Twenty-five per cent of the offices answering this question do not require any particular length of service before the employee comes under the plan; 5 per cent of those reporting require

from one month to three months; 8 per cent require three months; 14 per cent require six months, and 15 per cent require twelve months or more before employees come under the absence compensation for sickness and accident plan. Of those reporting, 27 per cent stated that it depends upon the record of the employee and 6 per cent of those reporting did not answer this question clearly. Attention is called to the fact that 69 per cent of those

Contribution by Employees. The answers to the question, "Does the employee contribute to a fund from which these payments are made?" were very interesting. We found that only 8 per cent of the offices reporting on this subject require the employees to contribute to such a fund. It is interesting to note that in the small offices only 3 per cent provide for a contribution from the employees while in large offices 13 per cent have this policy.

Compensation for National Guard Duty. Of the offices reporting on the question: "Is absence on account of National Guard duty compensated for?" 74 per cent compensate for this absence and 26 per cent do not. The percentage of offices that compensate for National Guard duty was about the same in all four groups. We, therefore, conclude that it may be considered a standard policy for offices to compensate for absence on account of National Guard duty. Some offices pay full compensation in addition to the compensation received by the employee from the government, while others just pay the employee the difference (if the government compensation is less) between the employee's regular compensation and the government pay for National Guard duty.

Compensation for Jury Service. Of the offices reporting on the question, "Do you compensate for absence on account of jury service?" 89 per cent pay for jury service while 11 per cent do not pay for such absences. The small office is just as liberal as the large office in this connection; in group one 91 per cent of the offices reporting pay for such absences, and in group four 92 per cent pay for jury service. A large number of concerns just pay

the difference between the amount obtained for jury service and the regular compensation of the employee.

Compensation for Religious Holidays. The percentage of offices providing compensation for religious holidays other than Christmas was about the same in all four groups. In groups one and four 61 per cent provide compensation for such absences. Sixty-two per cent of all offices reporting on this subject provide compensation for absence on account of religious holidays other than Christmas. It is interesting to note that more than a majority of the offices provide compensation for absence on account of the reason stated. In certain large cities, New York in particular, the policy of providing compensation for absence on account of religious holidays other than Christmas, may be considered as a standard working condition.

Per cent of total.....	...	62	1	37

Absence for Appointments with Doctor. A large number of offices provide compensation for absence from work because of appointments with dentists and doctors. Of the offices reporting, in group one 76 per cent provide compensation for such appointments and in group four 74 per cent do. Of all offices answering this question, 76 per cent provide compensation for absence for such appointments, 17 per cent do not compensate for such absence or do not allow same during office hours, 2 per cent do in some cases, and in 5 per cent of the offices it is discouraged during working hours. Most concerns feel that the employees' physical condition is a company interest and that deductions from compensation should not be made for time spent in safeguarding the employee's health. Our conclusion, therefore, is that it is standard practice not to deduct for time off on account of appointments with doctors and dentists during working hours where it is necessary for the employee to have the appointment during working hours.

COMPENSATION AND PROMOTION

Frequency of Salary Payments. The answers to the question: "How often are salaries paid?" show that of the offices reporting on this subject, 42 per cent make salary payments weekly, 50 per cent twice a month, and 17 per cent every month. In the larger offices the policy of paying twice a month is most popular and in the smaller offices the policy of paying weekly is most popular. The results show that it is standard practice to pay every week or twice monthly as 92 per cent of those reporting pay either once each week or twice monthly. Some of the concerns reporting on this question said that some of the employees in their offices are paid more frequently than others.

Compensation for Overtime. A greater percentage of the larger offices pay for overtime than of the smaller offices. In answer to the question: "Do you pay for overtime?" only 9 per cent of group one reported that they pay for overtime. In this connection, it is necessary to explain that, in all probability, many of these concerns pay "supper money" but the question was not asked on the questionnaire. In group four 29 per cent pay for overtime. Of the total of 302 offices reporting, 78 per cent do not pay for overtime other than supper money while 22 per cent pay for overtime. The results of this analysis lead one to the conclusion that it is standard practice not to pay for overtime other than supper money. There is a tendency in all offices towards cutting down overtime by increasing efficiency and production during regular working hours. In offices where a great deal of overtime is continually put in, tests have often shown that the total production of the

* Question not asked on questionnaire. No doubt many offices, doing so, did not report it.

Recognition for Long Service. The answers to the question: "Do you give special recognition for long service?" do not provide us with material to reach very definite conclusions. Of the 261 offices answering this question, 24 per cent give it no definite special recognition, 13 per cent give time off, 14 per cent give it definite consideration in salary increases, 4 per cent give bonuses, and 45 per cent give other recognition. Other recognition really means, in most cases, consideration in connection with salary increases. The standard practice may be said to be to give long service definite recognition in connection with salary increases. Other things being equal, the individual having the longer service record is, with most concerns, given preference for promotions. Some concerns give special recognition in the form of a service button, medal, or membership in an honorary organization to those having long service records.

Recognition for Good Attendance. Of the 234 offices reporting on special recognition for good attendance, 39 per cent give no special recognition, 10 per cent give time off, 15 per cent give it definite recognition in salary increases, 5 per cent give special bonus awards, and 31 per cent give other consideration. Here again, the standard policy is to take good attendance into consideration in connection with salary increases and promotions, rather than special recognition in the way of time off or bonuses. A number of offices use special contests to create interest in good attendance and award prizes to the winners. One concern reported good results from a plan of presenting two theatre tickets to each employee having a perfect attendance record for four consecutive months.

Reward for Worthy Suggestions. Very few offices have suggestion plans whereby awards are made to employees for good suggestions for improving efficiency or lowering operating costs. The replies to this question were not very clear but 31 per cent of the offices reporting state definitely that no

special recognition is given for worthy suggestions; of the balance of 69 per cent a few have suggestion plans in effect and others take it into consideration in connection with salary increases and promotions. Some concerns find it a good investment to provide the necessary machinery for a suggestion

Profit-sharing Plans. Of the offices reporting on the question: "Have you a profit-sharing plan for office employees?" 15 per cent have a profit-sharing plan while 85 per cent do not have such a plan. The profit-sharing plan is in vogue more in the smaller offices than in the larger ones. In group one 23 per cent have profit-sharing plans, in group two 13 per cent, in group three 18 per cent, and in group four only 9 per cent have profit-sharing plans. Some concerns have profit-sharing plans for executives but not for other employees.

Time between Salary Increases. Employees are given salary increases about as often in the small offices as they are in the large ones. Of the 286 offices reporting, 21 per cent have salary increases, on the average, every six months, 5 per cent more frequently than every six months, 44 per cent every twelve months, and 28 per cent were not definite. The results show that 26 per cent of the offices, answering this question, on the average, have salary promotions every six months or less and 46 per cent have increases on the average of more than six-month intervals. The policy of giving salary promotions once each year seems to be the most popular and is that used by the largest number of offices reporting.

SPECIAL PRIVILEGES

Personal Telephone Calls. Personal calls of employees on company telephones are permitted by 85 per cent of the offices in group one, 83 per cent

PERSONAL TELEPHONE CALLS

Group	Concerns answering	Allow	Allow but discourage	Not allowed	Charges		
					Charge for calls	Do not charge for calls	Charge in some cases

in group two, 66 per cent in group three, and 49 per cent in group four. This privilege becomes less and less frequent the larger the office. Of the offices reporting on this question, 70 per cent permit the use of telephones for personal calls, 25 per cent prohibit the use of the telephones for personal calls and 5 per cent discourage the use but permit it. Just 49 of the 214 offices that permit the use of telephones for personal calls charge for them. A large majority do not charge for the local calls of employees.

Smoking during Office Hours. Smoking is permitted during office hours in 56 per cent of the offices in group one, 39 per cent in group two, 19 per cent in group three and just 15 per cent in group four. Of the 302 offices reporting on this question 31 per cent permit smoking during office hours and 66 per cent prohibit smoking and 3 per cent discourage but permit smoking. This privilege is more perfect in the smaller offices; in the larger offices there is a tendency to prohibit smoking as in group four 82 per cent of the offices prohibit smoking during working hours.

Visits of Friends. Visits of personal friends of employees are permitted by more than a majority of the offices. Of those reporting on this question 43 per cent permit the visits of personal friends, 18 per cent permit but discourage such visits, and 39 per cent prohibit such visits. The small office is more liberal than the large office in this respect.

Handling of Personal Mail. Handling of personal mail for office employees is permitted in 58 per cent of the offices in group one, while 22 per cent prohibit and 20 per cent discourage the distribution of personal mail in the office. In group two 66 per cent, in group three 46 per cent, and in group four 38

distribution of personal mail in the office. While the distribution of personal mail is permitted in a majority of the offices, in many of them it is discouraged.

SERVICES FOR EMPLOYEES

Health and Recreation. These activities include first aid, home nursing, matron service, hospital service, rest rooms, noon recreation, athletic teams, social clubs, and picnics and outings. There was a gradual increase in the number of concerns participating in these activities from the smaller to the larger offices. Of the 303 offices reporting on this subject, 76 per cent provide first aid, 23 per cent home nursing, 40 per cent matron service, 38 per cent hospital service, 70 per cent rest rooms, 31 per cent noon recreation, 57 per cent athletic teams, 46 per cent social clubs, and 56 per cent picnics and outings.

SUMMARY

Standard Working Conditions. Arbitrarily letting the practice of 75 per cent or more of the 305 offices reporting, represent standard working conditions, we find from the results of the summary that the following may be termed standard working conditions in offices:

1. The hours of work on week days, excluding Saturdays, are from seven to eight hours per day. The hours of work on Saturdays are from three and one-half to four and one-half hours.

2. The vacation allowance is twelve working days with pay. From one to six months' service is required before vacations are granted, and in most cases the employee must have been in the service of the company before June first to be entitled to a vacation that year.

3. Compensation is provided for employees absent on account of accidents or sickness, the regular compensation of the employee being the amount paid. A certain length of service is required on the part of the employee before he or she is compensated on account of sickness and accidents, the length of service ranging from one month to twelve months.

Employees do not contribute to a fund from which absence compensation is paid.

Employees absent on account of National Guard duty are compensated for such absence. In many cases they are compensated for the difference between the amount received for National Guard duty and their regular compensation where their regular compensation is more than National Guard

compensation. This compensation is given in addition to the regular vacation allowance.

Employees are compensated for absence on account of jury service and in most of these cases they are given the difference between the amount received for the jury service and their regular compensation when the government compensation is less than their regular compensation.

Employees are compensated for absence due to deaths in their families.

Employees are compensated for time lost on account of appointments with doctors and dentists.

4. Salary payments are made either every week or twice a month.

Employees are not given compensation for overtime other than supper money.

Employees are given special recognition for length of service, the recognition varying according to the concern, it being, in some cases, time off, bonuses, publicity and, other things being equal, preference for promotion.

The average time between salary promotions is from six months to one year, the annual increase plan being the most popular.

5. Employees are permitted to use company telephones for personal calls and are not charged for these calls unless they are long distance calls.

6. First aid and rest rooms are provided for employees.

Policies in Effect in a Majority of Offices. In addition to, or in lieu of the standard working conditions mentioned above, from 50 to 75 per cent of the concerns reporting provide the following working conditions:

1. The working day, excluding Saturday, is composed of seven and three-fourths hours or less of work per day.

From three to four hours inclusive are the working hours for Saturdays.

2. From one month to six months of service is required before vacation allowances are made.

3. From one day to six months of service is required before compensation is allowed for absence on account of sickness and accidents.

Compensation is paid for absence on account of religious holidays other than Christmas.

4. Special recognition in the way of time off, bonuses, and, other things being equal, preference for promotion is given for good attendance.

Special recognition is given for worthy suggestions on the part of employees. This consideration takes the form of prizes, consideration at the time of salary increases, etc.

5. Smoking is not permitted during working hours.

Visits of personal friends are permitted but in some cases discouraged.

The personal mail of employees is handled in the office, but this is discouraged in some cases.

6. Company athletic teams are sanctioned and supported and picnics and outings are provided for employees.

7. Company loans, libraries, and group life insurance on which the premiums have been paid by the company are provided for employees.

Policies in Effect in Less than a Majority of Offices. In addition to, or in lieu of the above working conditions, from 25 per cent to 50 per cent of the offices reporting provide the following working conditions:

1. Seven hours or less of work on week days, excluding Saturday, and three and one-half hours or less on Saturday.

Rest periods, ranging from five minutes to thirty minutes per day, are provided.

2. From one month to three months' service is required before a vacation may be taken.

The Saturday preceding the vacation period is allowed as part of the vacation.

Extra vacation time is allowed when a legal holiday falls within an employee's vacation period.

3. There is no required period of service before compensation is paid for absence on account of sickness and accidents.

4. Salaries are paid weekly.

5. Matron service, hospital service, noon recreation and social clubs are provided for employees.

6. Company cooperative purchasing for employees, company stock purchase plans, mutual benefit associations, pensions, payroll deduction life insurance, and group savings plans are provided for employees.

Policies in Which the Small Office Is More Lenient. The following working conditions are provided by 25 per cent or more of the small offices included in groups one and two and are not provided by as many as 25 per cent of the larger offices included in groups three and four:

1. The Saturday preceding the vacation period is allowed.

2. Less than three months of service is required before employees are granted compensation for absence on account of accidents and sickness.

3. Smoking is permitted during working hours.

Attention is also called to the fact that personal mail for employees is handled by a larger percentage of small offices than by large offices. Visits of personal friends of employees are also permitted in a larger percentage of the small offices than in the large offices.

More Lenient Policies of Large Offices. Twenty-five per cent or more of the offices included in groups three and four, the larger offices, provide the following working conditions which are not provided in as many as 25 per cent of the offices included in groups one and two:

1. Rest periods during working hours.

2. Extra time off for long service.

3. Compensation for overtime. This is provided by 29 per cent of the offices in group four.

4. Matron service and hospital service are provided for employees.

5. Cooperative purchasing for employees, mutual benefit associations, pensions, evening schools, contributions to school tuition, and group savings plans are provided for employees.

Attention is called to the fact that in many offices the working conditions and privileges for executives are different from those provided for other employees. This is particularly true in connection with vacations, as in many cases, three- and four-week vacations are provided for executives having great responsibilities while just two weeks are provided for other employees. It was also noticeable that the offices located in larger eastern cities are somewhat more liberal in the working conditions provided for employees than those in the western cities although we have not prepared statistics covering this subject.

CONCLUSION

In conclusion it is hoped that this survey will be of value and assistance in making decisions regarding the working conditions in offices and that it will:

1. Act as a guide on the standard and average practices of offices with respect to working conditions and extra compensation plans.
2. Give those offices now giving better than average working conditions a knowledge of this fact and enable them to so inform their employees.

This knowledge will, no doubt, result in a return to the concern in the way of greater contentment, good will and appreciation of working conditions on the part of the employee.

3. Give those in charge of offices information as to whether or not the working conditions in their particular offices are as good, or not as good as the working conditions in other offices.

The office which is not now providing as good as the average working conditions will then, no doubt, consider the advisability of providing better working conditions. Such investigations will, no doubt, in many cases result not only in improved working conditions, but also in benefits to both the concern and its employees.

CHAPTER IV

SALARY ADMINISTRATION AND PROMOTION

By H. B. BERGEN, *Director of Industrial Relations, The Procter & Gamble Company*

A plan of salary administration and promotion is, after all, a type of incentive plan. An incentive plan, to be effective, must appeal to the stronger of the worker's desires. It is generally agreed that the worker (especially the office, technical, or supervisory employee) desires first of all a "fair" salary related to the importance of his position and his performance in that position, and an opportunity for salary adjustments and promotion commensurate with his capacity and demonstrated progress. Unless these desires are satisfied, we may expect only mediocre results from other personnel activities. Of course, other devices, such as sympathetic, impartial, and efficient leadership, are needed in addition to a sound plan of salary administration and promotion, but a recognition of individual differences by means of salary and promotional adjustments is fundamental to effective personnel administration.

The need for scientific salary administration and promotion is indicated by the following drawbacks of current practice:

1. Variability in starting wage or salary for new employees of equal ability in the same position.
2. Employees frequently held in one monotonous position simply because they perform the duties efficiently and in total disregard of their ability to fill a higher grade position equally well.
3. Individuals considered too valuable in their positions to transfer yet receiving no extra financial recognition for holding them in one type of work.
4. Promotion based on seniority and limited to vacancies in the department to which the employee has been assigned.
5. Inequalities in remuneration for similar work throughout a given institution.
6. Improper relationships between the remuneration of different individuals and their respective contributions to the production of the economic good created by the enterprise.
7. Salary and wage adjustments based on seniority rather than on merit.
8. Salary adjustments obtained by the employee advising the management of an outside offer.
9. Promotion without salary or wage adjustment.

Special mention should be made of the undue amount of emphasis which is at present given, either consciously or unconsciously, to seniority as a basis for rewards. This practice is in opposition to any attempt to recognize

individuality. There is nothing more deadening to the initiative of the newly employed worker than the knowledge that some older employee performing the same grade of work with the same or lesser degree of efficiency is receiving twice or three times the salary that the new employee receives, simply because of length of service. The same is true in the case of a new employee occupying a position requiring considerable technical training (*e.g.*, in accounting or statistics) finding out that the incumbent of some routine clerical position (*e.g.*, file clerk or registered mail clerk) is receiving the same rate of pay because of the latter's seniority. Unless this length of service factor is given only minor consideration in the development and operation of an incentive plan, effective appeal will never be made to the worker's strongest desires. We must, therefore, consider the worker as an individual rather than as a member of a group. Otherwise, there will be little incentive for individual efficiency and, consequently, submergence of individuality into group consciousness. There is a distinct need in many organizations for an equitable plan of salary administration and promotion, that is, one which will facilitate the making of satisfactory and satisfying adjustments between men and their work.

Methods of Procedure. The making of satisfactory adjustments, however, is dependent upon our ascertaining the facts—that is, the facts about each class of positions in a given organization and the facts about each employee—and upon our utilization of these facts. This requires the development and operation of certain methods of procedure, which we may classify as follows:

1. Methods of analyzing work and establishing position standards.
2. Methods of evaluating the capacities and abilities of each individual employee.
3. Methods of making salary and promotional adjustments.

The first step in the development of a plan of salary administration is an analysis of the objectives of the organization as a whole, of each department, division, section, and smaller unit, and, finally, of each class of positions. The facts revealed by such an analysis should result in the establishment of specifications which will define the duties and responsibilities of each class of positions in the given institution. These specifications should enable the management to group the various classes of positions together into grades, arranged in an ascending order of relative importance and difficulty. When this has been done, it is practicable to work out salary standards in terms of the relative "value" of each grade of work.

The next step is an analysis of each employee's characteristics, in comparison with the relative degrees of abilities possessed by all of the other employees. The facts and opinions disclosed by this process should be recorded as specifically as possible and should be made known to the employee and to the management.

With the facts about the work on the one hand and the facts about the employee on the other, the management is in an excellent position to make satisfactory and satisfying adjustments between each employee and his work. The successful making of such salary and promotional adjustments cannot fail to increase the worker's satisfaction from his work, to decrease the expen-

diture of his energy in the accomplishment of his tasks, and to increase the amount, quality, and speed of his productive output.

It is the purpose of this article to discuss these three methods briefly, with special emphasis on the methods of analyzing work and establishing position standards, and also to discuss the line executive's part in salary administration.

METHODS OF ANALYZING WORK AND ESTABLISHING POSITION STANDARDS

For the purpose of our discussion, the methods of analyzing work and establishing position standards may be classified into the following three divisions:

1. Job analysis and the establishment of specifications for each class of positions.
2. The grading of each class of positions and the establishment of a class of positions.
3. The analysis of rates of compensation and the establishment of salary schedules.

Job Analysis and the Establishment of Class Specifications. Job analysis is the process of studying all of the available facts about any given task, position, department, or other unit. The analysis of the flow of work, methods of procedure, utilization of office equipment, and the like may be considered as phases of job analysis. If the results of such analysis are written up in standard form, we have at our disposal a device known as a "position specification." It is usually the practice to establish specifications for each class of positions rather than for each individual post or position. Such specifications may be expanded into various degrees of refinement, such as manuals of procedure, procedure charts, standard practice instructions, standards of output (i.e., quantity and quality), etc., depending upon the minuteness of the job analysis. There is a distinct tendency to develop the process of job analysis to a degree of quantitative refinement which will permit the establishment of salary and wage plans based upon the measurement of individual output.

The scope of the job analysis program to be undertaken by any organization should depend upon the purposes of such a program. The usual *objectives of job analysis* include one or more of the following:

1. The development or improvement of the plan of organization.
2. The development or improvement of methods of procedure, office machinery, equipment, forms, layout, etc.
3. The establishment of more accurate units for budgetary control and procedure.
4. The conservation of the health of the office worker.
5. The development of better methods for training office employees.
6. The establishment of standards which will facilitate the selection and placement of employees.
7. The establishment of standards which will facilitate the establishment of a grading plan for each class of positions and the development of a plan of salary administration and promotion.

A job analysis program which would include all of these objectives is seldom undertaken, due in part to the fact that many points of view would be required and that the expense of such research would require an appropriation which few managements would approve. It is our plan, therefore, to consider job analysis only from the viewpoint of the selection, placement, promotion, transfer, and compensation of employees.

One of the first questions to be considered, after the objectives of the job analysis program have been decided upon, is "*Who should make the analysis?*" It is usually possible to enlist the efforts of everyone affected by the program. For example, each individual employee may be instructed to outline the duties and responsibilities which have been assigned him, and his supervisor requested to verify and revise this information. The greater the cooperation of all concerned, the more comprehensive and accurate will be the data collected. It should be emphasized that the responsibility for job analysis is that of the supervisors, department heads and other executives. On the other hand, it is the function of the personnel staff to facilitate this process of analysis by consultation and conference with the executives and rank-and-file workers, and by editing the specifications in standard form.

Another important question is: "*How should the analysis be made?*" There are, of course, good and bad methods of job analysis. The use of questionnaires supplemented by interviews is an example of current practice. Such methods are excellent for the purpose of enlisting the cooperation of the supervisors and the rank-and-file employees. Figure 1 indicates a type of questionnaire which has been used successfully in office organizations. From the standpoint, however, of insuring accuracy, completeness, and uniformity in the development of specifications, it is desirable that the information obtained by the use of questionnaires and interviews be verified if possible by the objective observation of a trained research worker. The final specifications which are established should represent agreement between the employees, supervisors, and personnel staff as to the standards for each class of positions.

The actual preparation of a position specification may be illustrated by outlining the excellent technique which has been developed by the American Council on Education. According to this technique, the specification proper should be preceded by a "brief statement defining the general nature and location of the work." The detailed statements of the work itself, which follow, are called "objectives." The instructions for preparing a statement of these detailed objectives are reproduced in the Appendix of this article.

A specific example of the utilization of this technique in a large public utility company appears in Fig. 2 as a specification for the class of positions known as "equipment job order man" in that organization.

Up to this point the discussion of job analysis has dealt with the qualitative aspects of the analysis process. Qualitative job analysis must, of course, precede any attempts to quantify the various elements of any class of positions. But, if we are to make progress in the development of specific incentive plans which will supplement the basic salary incentive plan, it will be necessary to answer not only the question "What?" but also "How

Statement of Duties

Please read over the entire statement first, and then fill out, answering each question carefully and fully. Use additional sheets in case spaces provided for answers are insufficient.

Name.....
 Title.....
 Department.....
 Division.....

1. What is the customary title of your position?.....
 2. What is the location of your place of work?.....

(City)

(Bldg. or Street No.) (Room No.) (Telephone—Local No.)

3. Who is your immediate superior?..... (Name) (Title)
 4. How long have you been in your present position?..... With Company?.....
 5. If you are responsible for the direction or supervision of others, give their titles or occupations, the number of employees under each title, and (if space permits) give their names, at least the names of those who have any supervisory duties:

6. What are your regular working hours? From..... to.....
 with..... minutes off for lunch. Net hours per week.....

7. Do you give any time to work in any other position?.....
 8. List (1) all reports you prepare, and (2) all records you keep. Attach one sample of each, properly filled out with headings and typical entries.

9. Has a standard been assigned to you on the amount of work to be performed each day?.....
 If so, what is the amount?.....

10. Describe your work. Make your statement as detailed as space will permit. Put it in paragraph form, one paragraph for each principal kind of work under each heading. Mention by name and number of the forms and records used in the respective kinds of work. List your daily routine duties first and then list such additional duties as are performed weekly, monthly, on special occasions, or to fill in.

Use appropriate column for estimate of time normally spent on each kind of work.

Days per Mo.	Hrs. per Day	% of Total
--------------------	--------------------	------------------

Daily Routine Work:

Periodical Work (Done Regularly but not Daily):

Special and Fill-in Work:

11. When you took up your present duties, how were instructions given you regarding them? Were your duties definitely and clearly assigned? What training did you receive as to the best methods of performing your duties?

12. Are you taking educational courses or otherwise preparing yourself for advancement? If so, give particulars as to the methods followed and the position in mind.

Note: You are especially requested at this time, in addition to filling out this statement, to send in suggestions, under the provisions of the Suggestion System. Do not fail to submit any suggestions which you believe would make for efficiency and economy. Send them in on any subject, and especially on matters effecting your own position, in reference to one or more of the following:

- (a) Reassignment of duties:
 (b) Rearrangement of desks and other equipment:
 (c) Greater use of labor-saving appliances:
 (d) Savings in supplies:
 (e) Elimination of non-essential records:
 (f) Shortening of routines:
 (g) Cutting down the number of motions in actual work:
 (h) Reducing the number of absences:
 (i) Changes in policies:
 (j) Improvements in the work of others:

much?" In other words, we must *measure quantitatively* the various elements which have been qualitatively established by objective observation. A discussion of the technique of quantitative job analysis would be beyond the scope of this article. A specific example, however, of the establishment of

(This specification for the class of positions known as "Equipment Job Order Man" in a large public utility illustrates the use of the technique of job analysis which has been developed by the American Council on Education.)

Equipment Job Order Man

Prepare job orders for minor additions to and changes in central office equipment and large private branch exchanges.

Located in Equipment Plans force.

OBJECTIVES

Apply, when necessary, any knowledge or experience gained prior to entrance as a new employee.

Gather information in sketch and note form, from existing installations, or from records, for use in formulating plans.

Determine how any special construction and maintenance features of job are to be met.

Select the standard circuits and equipment best suited to the job.

Determine if there is need for special circuits or equipment.

Decide on proper arrangement of equipment on floor, switchboard, frames, racks, etc.

Conclude on best method of cabling and wiring.

Confer with superior on tentative plans for obtaining suggestions on his preliminary approval of them.

Direct draftsman in making working sketches and drawings of equipment, floor plans, cabling and circuits layouts.

Prepare lists of apparatus, cabling, circuits, drawings, etc., for job.

Estimate construction, removing, rearrangement, depreciation and salvage costs.

Prepare lists of job orders according to approved practices.

Edit requisitions for equipment needed.

Write letters covering subsequent modification of plans.

Answer questions of manufacturer or installer regarding proposed changes.

Cooperate with those engaged on power plans, if job has any power features.

Comply with Company regulations, as to hours, conduct, etc.

Read and study on the training subjects recommended for this assignment, as an aid to self-improvement.

Development proficiency in this work as a requirement for advancement to Specification Man.

FIG. 2.—Class specification.

quantitative specifications for the class of positions known as "Addressograph Operator" in a well-known office organization is shown as Fig. 3. This case is indicative of the application of quantitative job analysis to office

operations. On the basis of such measurement of individual output, it is possible to develop premium and bonus plans for certain classes of positions.

(This is an example of the use of quantitative job analysis in an office organization for the purpose of establishing quantitative specifications for the class of positions known as "Addressograph Operator." Reference: I. O. Royse—*Determination of Work Units for Office Machines*, 1927, American Management Association.)

Addressograph Operator—The cycle of work at the addressograph machines, model F-1, consists of seven elements:

- | | |
|---|--------------|
| 1. The operator receives the job ticket, material to address and a time ticket "rung in" | .33 minutes |
| 2. The plates specified are taken from the file..... | .75 minutes |
| 3. Plates are placed in the machine..... | .62 minutes |
| 4. The operator takes a working supply of the material to be addressed and places it face down on the left side of the machine table..... | .15 minutes |
| 5. The operator feeds the machine with left hand, material face down, and removes and turns it over with right hand. A foot lever is used to regulate the speed of the machine..... | 1200 per hr. |

Note: A helper inspects the work for defects.

If necessary it is immediately returned to the operator who adjusts machine and re-runs defective work, or helper makes the corrections by hand.

- | | |
|--|-------------|
| 6. If other trays of plates are to be used for the same job the operator returns used plates to the filing cabinet and repeats operations Nos. 2 and 3...65—about .001 per address plate | |
| 7. When the job is completed the time ticket is rung out..... | .30 minutes |

The unit finally determined is based upon element 5. Study of this element shows that 1,200 pieces per hour is a basic average on a straight run. It also shows that there is approximately one job change requiring two and one-half minutes to each 150 pieces addressed. In one hour six jobs of 150 can be completed. An allowance of 12 $\frac{2}{3}$ per cent is made on this operation reducing the expected output from 900 to 800 units per hour.

FIG. 3.—Quantitative class specification.

The Grading of Classes of Positions. A class grading plan represents the grouping into grades of the various classes of positions, arranged in an ascending order on the basis of relative importance, difficulty, and scope of activities. For the purposes of our discussion, let us assume that a "position" is a group of duties, responsibilities, or activities which are assignable to one individual, and that a "class" is a group of positions which are practically identical from the standpoint of duties. A "grade" would be a group of classes of positions which involve duties of approximately the same scope, importance, difficulty, and value without regard to the department or type

of work involved. The development of a class grading plan should not be confused with the setting of salary scales or with the rating of individual employees. A grading plan considers the classes of positions and not the incumbents of these positions.

The class grading plan provides a definite basis for the development of lines of promotion and for the establishment of salary standards. Without such a plan, we can seldom be certain that the adjustment of an employee from one position to another is not in the nature of (1) a demotion, which would be an injustice to him if the adjustment were intended to be a promotion or a transfer, or (2) a promotion, which would be an injustice to the other employees if the adjustment were intended to be a transfer or a demotion. In addition, it is practically impossible to eliminate departmental lines when a promotion is to be made unless a class grading plan has been established in advance. A grading plan is a prerequisite also to the development of a salary plan. In order that there be uniformity of compensation for the same grade of work throughout the company, it is necessary to determine definitely in advance the relative grade of each class of positions.

In developing a class grading plan, the following principles should provide a basis for the grading of each class of positions:

1. The scope of the duties and responsibilities of the positions of any given class, as indicated by the specifications and by comparison with others, should be the principal factor which determines its grade.
2. The education, experience, skill, etc., required of the incumbents of the positions of any given class constitute an auxiliary basis for determining its grade.
3. The skill, efficiency, compensation, etc., of the present incumbent of a position of any given class should have no bearing in determining its grade.
4. The simplest practical grouping of classes should be adopted which will serve the purposes of the grading plan.

The acid test of the effectiveness of any grading plan is whether it commends itself to the major executives, supervisory employees and rank-and-file workers. It is desirable, therefore, that all concerned participate in its development. The preparation of the first draft of the plan should be the responsibility of the personnel staff, working in close cooperation with the rank-and-file and the supervisory employees. The final grouping and arrangement of the various classes of positions should be worked out by a conference committee of executives, who have been appointed for this purpose by the chief executive. This final draft of the plan should represent the agreement of all concerned as to the relative importance of each class of positions.

There are various methods of actually determining the grades of any given class. The two which are most frequently used are the grade description method and the class rating method. Often both are used, the one as a check on the other.

The *grade-description method*, by utilizing the organization chart and the specifications, recognizes definite grades of work, which are first established and defined, the various classes of positions being then assigned to the proper grades by placing key positions first and making comparisons and inter-

(This is an example of the grade description method applied to a number of similar office organizations. Reference: M. A. Bills—A Method for Classifying Jobs and Rating Efficiency, Vol. I, *Journal of Personnel Research*.)

A. Including supervision over B, or highly technical work for which special training is necessary.

B. Supervisions of any C work or a large unit of lower grade work.

C. Operations requiring knowledge of the general principles of the business or some other general field and involving analytical thought.

1. Has a command and applies general rules or principles to cases not previously covered, or uses information which can be acquired only outside of Company, or persons who, through long experience with the Company, have acquired and are exercising knowledge of the general principles of business.

2. Same as 1, only handles more complicated cases.

D. Has complete charge of small unit of work in class E or a large unit of lower grade work, or assists in supervision under A of E grade work or lower.

E. Operations of classification, examination, review, compilation, of calculation, other than simple, involving complete and intensive knowledge of a restricted field.

1. Operations involving the intensive knowledge of a restricted field and the taking of action on cases not definitely covered previously or the making of other than simple calculations.
2. Checking, handling of papers where question has arisen and adjustment of difficulties in the above, making of special calculations, or performing of more complex E-1 operations, or conducting correspondence in a restricted field.

F. First grade supervision. Supervision of I, H, or G work in small groups.

G. Operations requiring identification and manual dexterity, and in addition assembling, combining or simple calculations (following a variety of rules, which are, however, very definite and specific).

1. Transcribing which involves work of above nature, or a variety of B work, or work requiring subsequent follow-up. Subject filing.
2. Checking or adjusting difficulties in the above work.

H. Simple operations requiring identification and manual dexterity. This requires the use of a few definite rules. It includes those jobs where only a regular and definite change is made in the material handled and in no case includes jobs where a large variety of rules must be understood and applied.

1. Simple filing or transcribing, or machine operations requiring no technical knowledge (such as addressograph).
2. Checking above work, responsibility for small unit of same, or doing above work without subsequent check.

I. Office boys, messenger service, simple clerical duties such as simplest sorting, etc., handling simple machines, such as letter press, etc. Major portion of time on messenger work.

FIG. 4.—Class grading plan.

polations. The effectiveness of this method is dependent upon the possibility in any given organization of preparing simple, distinct, and clear-cut generic

(This is an example of a simple rating scale which is used as one basis for determining the relative importance of each class of positions in an office organization. Reference: E. H. Little—*Some Considerations in Installing a Salary Administration Plan*, 1927, American Management Association.)

General Education—Maximum Points 6. The degree of general education, attained through school or individual study, necessary to give background for all-around performance in the position.

Special Training and Experience—Maximum Points 8. The amount of training in special courses, and experience in previous positions required by position in question.

Special Knowledge—Maximum Points 6. The amount of specialized knowledge of the functions of the department required to perform the work.

Accuracy and System—Maximum Points 6. The necessity for accuracy in copying, posting, checking or machine operation, and the need for system and neatness in performance of work.

Ability to Plan, Execute and Accept Responsibility—Maximum Points 8. The extent to which position requires the ability to plan for self or others, to carry out policies, and to be responsible for results.

Supervisory Ability—Maximum Points 4. The degree to which successful performance in the position requires the ability to direct others and to obtain their cooperation for the attainment of results.

Judgment—Maximum Points 6. The degree to which position requires the exercise of discriminating judgment, and the ability to arrive at logical conclusions.

Mental Ability—Maximum Points 3. The mental alertness necessary to sense the significance of facts and situations, or to grasp and remember a multitude of details.

Ability to Make Good Contacts—Maximum Points 4. The extent to which position requires a personality which can make a prepossessing impression for the department or the company.

Integrity and Professional Ethics—Maximum Points 4. Degree to which position requires a person whose integrity has been proved, and whose discretion regarding people and things can be depended upon.

FIG. 5.—Scale for rating classes of positions.

definitions of the various grades. In Fig. 4 is reproduced a class grading plan which resulted from the utilization of the grade description method.

The *method of rating classes of positions* is based upon the use of a rating scale which consists of the more important of the factors which differentiate the higher from the lower grade classes. Some scales provide for an elaborate series of factors and weights by means of which an index number is obtained for each class of positions rated. On the basis of this index number, a given class is assigned to a definite grade. The success of any scale, however, is dependent upon the value of the opinions of the individuals who are doing the rating rather than upon the scale itself. Increasing the complexity and numeration of a rating scale does not in any way increase its reliability, objectivity, and validity. A simple scale is probably the more workable. An example of a scale for rating classes of positions is shown as Fig. 5.

A third method of *grading classes* which has not been used as extensively as the other two is the *grade progression* method, by which, starting with what are obviously the least difficult and important classes, like classes of positions are considered one by one and are grouped together into grades as they (the classes) increase in difficulty, importance, and relative value, until the classes of the highest quality have been reached. The grading plan which resulted from the application of this method in one organization appears as Fig. 6.

Grades are real and fundamental distinctions, but whether these or other distinctions are used in the final grading plan which is established is, of course, an arbitrary matter. Nevertheless, if a class grading plan has been worked out carefully, and accepted by those who either use it or are affected by it, it will be found indispensable in the development of a plan of salary administration and promotion.

The Establishment of Salary Schedules. The working out of equitable salary schedules is, of course, the most difficult problem which must be solved in the development of a plan of salary administration having as its principal objective the satisfaction of the worker's desires. No practical remedy has as yet been suggested for the dissatisfaction arising from the unequal distribution of the world's economic goods. Nor have any of the social sciences advanced any acceptable theory as to what should be an equitable and ethical division of the earnings of a given business organization. At the present time, therefore, the most practical policy seems to be to compensate the employee in proportion to his contribution to the production of the goods or services created by his company.

The application of such a policy involves a determination of the relative value of the class of positions to which he is assigned and an evaluation of his relative worth at any given time in his position. The determination of the relative value of each class of positions is, of course, the problem of developing a class grading plan. This has been discussed in the previous section of this article. The problem of evaluating the employee's relative worth, however, will be discussed later.

After the relative value of each class of positions has been determined, we are in a position to establish definite schedules of pay for each grade of work.

A plan of salary administration assumes that the basic rates of pay should be uniform for the same grade of work throughout an organization. The

current trend in salary practice, therefore, is to establish definite minimum and maximum rates of pay for each grade of work and to indicate intermediate step rates between the minimum and maximum. In establishing such minima and maxima, there is usually overlapping, inasmuch as it is assumed that an experienced man in one grade is worth more than a beginner in a position in a higher grade. The differentials between the minima

FIG. 7.—A graphic presentation of minimum and maximum salary rate gradations by grades.

and maxima increase with the increase in grade. In addition, the increments of increase between the maxima of successive grades and between the minima should be proportional to the increase in grade. The working out of salary schedules in conformance with these principles may be adapted to meet the conditions within any organization or community. Current so-called "market rates" for certain classes of positions will influence the determination of some of the minimum rates. Interchange of information on salaries between companies will also be of help, although such information is of little value without definite specifications for the class of positions being investigated.

The salary schedules may be represented by a graph, consisting of two curves (minima and maxima) of constantly increasing slope. Examples of the use of such graphs are reproduced in Figs. 7 and 8. In the first case, the salary rates are plotted along the vertical axis and the grades along the horizontal. The salary range for any given grade would be the increment between the points of intersection of the two curves and the vertical line which represents that grade. In the second case, semilogarithmic paper is used, the salary rates being plotted along the log scale. By plotting the maxima and

FIG. 8.—By plotting the maxima and minima as straight lines on a logarithmic scale, a constant even percentage increase in slope is obtained.

minima as straight lines an even percentage increase in slope is obtained.

The actual construction of a salary schedule table is illustrated by the example shown as Fig. 9.

If quantitative work standards have been prepared for any given class of positions, it is possible to augment the salary schedules by the development of a premium or bonus plan for that class. We must keep in mind, however, that these specific incentive plans apply to specific classes of positions rather than to the working force as a cohesive unit. They undoubtedly possess merit and tend to increase the worker's production. But they cannot be

* NOTE: These figures simply constitute a mathematical table. They do not represent rates for any particular organization.

applied at the present time to all classes of positions in any given organization. What is needed is a more comprehensive and basic compensation plan which will appeal to each individual employee. Such a plan should be in operation before specific incentive plans are developed for specific classes of positions.

METHODS OF EVALUATING THE CAPACITIES AND ABILITIES OF EACH INDIVIDUAL EMPLOYEE

We have discussed in some detail the methods of analyzing work and establishing position standards. The next step is to consider the methods of evaluating the capacities and abilities of each employee. In order that adjustments be made intelligently, it is necessary not only to have the facts about each position but also to have the facts about each employee. With these two sets of facts in hand, we are in a position to make adjustments between the employee and his work.

The principal methods now in use for evaluating employee characteristics include:

1. Periodic and special interviews.
2. Psychological and educational tests.
3. Ratings.
4. Attendance and punctuality records.
5. Medical records.
6. The personal history blank.
7. Reports and recommendations of superiors.

It is not within the scope of this article to discuss these methods inasmuch as they have been adequately discussed elsewhere. Mention might be made, however, of the desirability of posting to a central qualification record for each employee the information obtained by the above and other methods. The central qualification card, on the one hand, which gives a cross-section of the employee's characteristics, and the class specification, on the other hand, which gives a cross-section of the content of the position, together constitute the facts necessary for the making of adjustments.

It should be mentioned, also, that some form of a position record will be of great assistance. Such a record should show at any given time: (1) the present positions, arranged according to the plan of organization; (2) the grade and salary range for each position; (3) the present incumbent of each position; (4) the present salary of each of these incumbents.

METHODS OF MAKING ADJUSTMENTS

The principal adjustments which are made between men and their work are (1) salary adjustments and (2) promotional adjustments. The practices which have been followed in a large office organization in each of these two types of adjustments will be presented here because they illustrate the effective utilization of the various standards which have been discussed previously. In this company, it is the responsibility of the employment division of the personnel department to assist the line executives by facilitating:

1. Salary adjustments, which will recognize the relative worth of an employee within a given position.

2 Promotional adjustments, which will continuously and satisfactorily utilize the abilities and capacities and satisfy the interests of an employee.

Salary Adjustments. The making of salary adjustments will be considered under the following three headings:

1. Adjustment of the entrance salary.
2. Adjustment within the limits of the position for:
 - a. The average employee.
 - b. The exceptional employee.
 - c. The below average employee.
 - d. The employee receiving the maximum salary rate for his position.
3. Adjustment at promotion.

Adjustment of the Entrance Salary. The agreement with the applicant under consideration as to a fair and acceptable entrance salary is the first salary problem to be faced. Before attempting to fill a position the employment division will ascertain from the class grading plan and the salary schedules the grade of the position and the entrance and maximum salary rates. Next, it will consult the class specification for a description of the duties to be performed. A new employee enters at the minimum salary. Bargaining with the applicant is thus avoided. All of the available facts regarding the position are laid before him, including an explanation of how the salary rates have been arrived at. If an employment division has made a judicious selection, and the applicant is qualified, but not over qualified, for the duties and responsibilities of the position, the salary offered should, and usually does, appeal to him as a fair starting wage.

Adjustment within the Limit of the Position. The second problem is the making of salary adjustments within the salary limits of the position.

a. *The Average Employee.* It is the policy under the plan of salary administration normally to make adjustments on the anniversary of the employee's employment. The procedure is as follows:

The employment division notifies the department heads each month of the employees whose anniversaries occur during that month. A check-sized form, known as the salary adjustment review, is prepared for each employee who is to be considered and is forwarded to the department head. This form supplies the department head with data relative to the grade, salary limits, and step rates of the position, and the date and amount of the last three salary adjustments of the incumbent, and it provides a space for his recommendation. The department head recommends an increase, normally to the next step rate, or he indicates that he does not believe an adjustment is desirable. He then returns the form to the personnel department for review. The employment division, from the various records at its disposal, reaches a conclusion regarding the desirability of the proposed increase. These records include complete data of the employee's history with the company, his recent salary adjustments, his periodic ratings by the department head, and his educational activities. If the employment division is in concurrence with the department head, the form is routed through the budgetary procedure to the pay-roll division. On the other hand, if the employment division does not agree with the department head's recommendation, the problem is discussed with the latter until agreement or intelligent disagree-

ment is reached. If agreement is not reached, the problem is referred to the chief executive. This latter condition, however, seldom occurs. It should be emphasized that, although authority of approving these recommendations has been delegated to the employment division, authority for disapproval is retained by the chief executive.

The procedure outlined above covers the average case and it is believed that it will adequately recognize the progress of the majority of employees. It is, however, flexible in its application.

b. The Exceptional Employee. The department head uses discretion, of course, in recognizing individual differences. The amount of salary received by any employee within the limits of a position is governed by his relative efficiency in performing the work. The department head rewards unusual ability by recommending special adjustment at any time the employee's performance and progress have proved exceptional. When the department head wishes to recommend a special adjustment he requests the employment division to send him a salary adjustment review form. Otherwise the procedure is the same.

c. The Below-average Employee. On the other hand, no adjustment on the anniversary is made for the employee whose progress has not been satisfactory. The occasion offers the department head or supervisor an excellent opportunity to discuss frankly with the employee his unsatisfactory progress.

d. The Employee Receiving the Maximum Salary Rate for His Position. No adjustment is made above the maximum salary established for the position. In cases where an employee has reached this maximum salary, a memorandum reminding the department head of this fact is sent out by the employment division instead of the usual salary-adjustment review form. This letter requests the department head's recommendations as to what, if any, promotional or other adjustments he deems advisable. The letter also requests that he explain the situation fully and frankly to the employee. At this time also the employee is usually called to the employment division for an interview. He is told frankly that his promotion depends: first, on the frequency of openings in higher grades and second, on his ability to qualify himself for these positions in competition with other employees. If, in the opinion of the department head and the employment division, the employee has reached the limit of his capabilities, he is so advised. It is sympathetically pointed out to him that it is his problem to decide whether he wishes to remain in his present status or whether his opportunities for promotion would be better with some other organization.

Adjustment at Promotion. When making promotions it is the policy to adjust the employee's salary to the minimum rate established for the new position. In cases where the salary of the individual promoted is already at or above the minimum salary of the new position it is usual to make an adjustment to the next step rate. There are exceptions, however, to this policy. In cases where the employee who is being promoted has received a salary increase within two or three months prior to the time of promotion, further adjustment is usually not made immediately. There is also the special case of an employee who is not thoroughly qualified for the new position at the time he is promoted, but who promises to qualify rapidly as

soon as he is in the position. His salary is brought up to the established minimum by adjustments made during the first six, eight, or twelve months in the new position.

Promotional Adjustments. Continuous adjustment of the changing interests and capacities of the employee is dependent upon the machinery of an adequate promotional plan.

It is the policy of the company to fill all vacancies by promotion from within the organization whenever a qualified candidate can be found and to promote the best qualified individual regardless of whether he is in the particular department in which the vacancy occurs or in some other.

1. *Establishing the Grade of the Position to Be Filled.* The employment division is notified by a requisition form whenever a replacement is to be made or an addition to the force is needed. If a new position is to be created, the requisition is referred to the personnel research division for the purpose of analyzing the duties to be performed and tentatively grading the position. On the other hand, if the position to be filled has been previously established, its grading is ascertained by comparing the requisition with the class grading plan and its content by consulting the existing class specifications.

2. *Selection of the Candidate.* The first step in selecting a candidate for promotion is a careful consideration of all employees in the organization who may possess the necessary qualifications. The names of incumbents, irrespective of department, in positions a grade or two below that in which the vacancy exists are secured from the tabulating card records maintained by the records section of the employment division. It is then the problem of the employment division to select the best qualified person from this list. Various records are consulted in order to reach a decision as to the qualifications of the candidates. Chief among these is the centralized qualification record containing the employee's photograph and giving his age, marital status, past and present educational activities, previous employment record, history with the organization, and abstracts of all notes made during periodic interviews. The employee's folder containing his original application and his periodic ratings by department heads is also consulted. When this has been accomplished some of the names on the list will be automatically eliminated because of lack of special training or because of interests in other directions.

An employee who is receiving the maximum salary of his present position receives very careful consideration, but he is never recommended for promotion unless he is as well qualified as any other candidate.

Before the selection is made, it may be advisable to interview the line supervisory staff and the employee under consideration without necessarily divulging the purpose of the interview to the latter.

3. *Securing the Agreement of the Department Manager.* In many cases the candidate will be located in the department in which the vacancy has occurred, and it is necessary only for that department head and the employee to be agreeable to the change. On the other hand, in cases where the promotion is interdepartmental, it is necessary first to obtain the agreement of the head of the department in which the employee has been working. When and if this has been obtained, the approval of the prospective department head

and of the employee himself follows. If the employee does not desire this particular promotion for himself, it is not made. The same procedure is followed in filling the vacancy created by the promotion and, again, in filling the vacancy created by the second promotion, and so on, down through the different grades. If these chain promotions can be filled from within the organization, the new employee to be secured from the outside should enter in grade I. If a time-honored saying may be indulged in, it may be said that when the president dies a new office boy should be hired.

In many instances, when openings have occurred in the higher grades, half a dozen or more people have been advanced, each receiving an increase in salary, and yet the net pay roll cost to the organization has been decreased.

It should be mentioned that the employment division has found it exceedingly difficult to effect interdepartmental promotions during periods when, due to reorganization of old or the installation of new departments, the class grading plan temporarily has not been up-to-date. On such occasions, it has often been impossible to establish definitely that an apparently desirable move would actually result in an advancement in grade for the employee. Unless a department head can be assured that a transfer of a desirable employee will offer greater immediate and ultimate salary opportunities than he can offer, he is quite naturally unwilling to lose a valuable man.

THE RESPONSIBILITY OF THE LINE EXECUTIVE IN SALARY ADMINISTRATION

The successful application of a plan of salary administration and promotion will depend in no small part upon the appreciation of its value by the line executives and supervisory employees. It is essential, therefore, that they be trained by means of various training devices in the use of class specifications, the class grading plan, salary schedules, methods of evaluating the qualifications and progress of employees, and methods of making adjustments. Also, they should be trained in the specific difficulties of supervision as regards the making of salary and promotional adjustments. Two of the more important of these difficulties, namely, the interpretation of salary policies and decisions and the maintenance of a frank relationship with subordinates on salary matters will be discussed below.

Interpreting Salary Policies and Decisions. It is the responsibility of the executive to interpret properly to his subordinates the salary policies and decisions of his superiors. Unfortunately, this responsibility is not always accepted by him. We are all familiar, for example, with the case of the foreman who complains to his men that he would like to raise their wage rates but that the management will not let him, or with the case of the clerical supervisor who tells one of his clerks that the latter is worthy of a salary adjustment but that the management refuses to allow it. In other words, such executives lose sight of the fact that they were appointed to their positions by the management and not elected by their subordinates. They "sell" themselves to their subordinates at the expense of "unselling" the management. They attract a false personal loyalty to themselves, at

the same time developing a disloyal attitude on the part of the employees toward the organization. Such practices obviously undermine organization structure and break down morale.

If the management of an organization promotes or appoints an individual to an executive or supervisory position, he becomes a representative of management and should assume full responsibility for all management decisions on salary matters. This does not mean that the subexecutive should suppress his own honest convictions; it implies that, when his superiors do not concur in his recommendations, it is his obligation to present his difference of opinion to the management—who will usually explain their decisions—rather than to his subordinates, whose experience and judgment in most cases would not equip them to form a sagacious opinion. Confidence that there is a sound reason for every decision on salary matters made by the management should be the basis of his concurrence in decisions the reasons for which are not apparent. It is his privilege, of course, to ask for explanations, but where his limitations of experience will not enable him to appreciate the management's decisions, it is his obligation, as an appointee and representative of the management, cheerfully and confidently to acquiesce.

If he is a foreman, he should explain carefully to his workers the reasons for the wage rates and should indicate his full agreement with these standards. If he does not agree in all cases, he should take steps through proper channels to recommend changes in rates to the management, but he should not under any circumstances indicate to his subordinates that he is not in full agreement with the existing standards. If he is directing the work of salaried employees, he should make sure that each subordinate understands the basis of his individual salary rate, namely, the value of his position to the organization, and the recommendation of his superior in accordance with his individual performance on the job. The subordinate should realize that his present rate of pay is the reflection of his chief's appraisal of the value of his position and of his progress in this position.

To be specific, let us assume that you, the reader, are an executive and that one of your subordinates approaches you with a request for a raise in salary. Just how should you proceed? The following is suggested:

1. Tell your subordinate that you will be very glad to discuss his salary problem with him and invite him to present his views on the subject. Listen to him sympathetically, and then tell him that you will give the matter careful consideration and will let him know your decision in a day or so. Do not state that you will try to get a raise for him or that you will see what can be done about it. Simply agree to review the matter.

2. If you feel he is not entitled to a salary adjustment, interview him as soon as possible and so advise him frankly, giving him your reasons. Do not delay advising him and do not evade a frank statement of your opinions. Also, do not under any circumstances follow the familiar line of least resistance and recommend an adjustment when you know that it is not merited; such action is an expression of moral cowardice, betraying the interests of the organization and distorting the position of the employee. Do not pass the responsibility for the decision on to any one else, but bear in mind, nevertheless, that the subordinate has the right of appeal to your chief without fear of prejudicing you.

3. If you conscientiously believe that a salary adjustment should be made, make your recommendations through proper channels, but do not as yet indicate to your subordinate what your decision is.

4. If your recommendation is approved, interview your subordinate as soon as possible and advise him just what adjustment you are making and why you are making it. Do not let him first discover the adjustment in his next payroll envelope.

5. On the other hand, if your recommendation is not approved, interview your subordinate and tell him that, after careful consideration, you believe that no adjustments should be made at this time. Take full responsibility for the final decision and do not fail to support the management's point-of-view. Only the timid and cowardly executive will avoid this full responsibility.

Relationships with Subordinates on Salary Matters. It is also the responsibility of the line executive to maintain a frank "open-book" relationship with each subordinate as regards the latter's progress, salary, and chances of promotion. Although it is generally agreed that such a relationship is the only one satisfactory in the long run, executives frequently lack the courage to maintain it. We are all familiar with the case of the subordinate who, when notified that his services are unsatisfactory and that they will no longer be required after a certain date, is painfully surprised and complains that his chief had only a few weeks before told him that his work was satisfactory, this executive being the man who now requests the separation.

We are familiar, also, with the problem of the mediocre employee who is allowed to tag along year after year, being recommended now and then for transfer, for promotion, and for salary adjustment, but never for removal, simply because some executive has been a moral coward. This soft-hearted and probably well-meaning executive does far more harm than good, creating in the mind of the subordinate a false impression of his own usefulness and, through postponing the necessity for his vocational readjustment, may delay until it is extremely difficult or impossible for the misfit to realign himself. The injustice is by no means one sided, for the management also suffers. Years afterwards the organization discovers that there is a misfit on its hands, that the relationship between this employee and his work is neither satisfactory nor satisfying, and that his salary is considerably out of proportion with the value of the work. If an attempt is then made to separate this hapless individual, the act is condemned as inhuman and unjust.

Such situations can be avoided by any executive who will deal with his subordinates on a frank basis, keeping in mind that most people appreciate a candid, constructive discussion of even their faults. To be more specific, assume again that you, the reader of this article, are an executive supervising the work of six or seven subordinates. How can you maintain a frank, open-book relationship with them? The following suggestions are offered:

1. Interview each subordinate periodically, say three or four times a year, and tell him frankly just where he stands, what progress he has made during the last few months, why his rate of pay is what it is, what mistakes he has made and how he can avoid them in the future, and what his shortcomings are. Do not hold anything back. Let him know how he compares with each of his associates. If he has the ability to qualify for a higher grade job,

point out the opportunities for promotion and tell him how he can make himself worthy of them. But, if he has reached the limit of his possibilities, or if he is incompetent, tell him so without reservation; do not under any circumstances evade this responsibility.

2. Make certain that each of your subordinates knows that he can at any time discuss with you any problem, particularly such as a request for salary adjustment or a complaint. Encourage him to state his opinions and grievances without reservation at all times and make him feel that his position will in no way be jeopardized if he criticizes your decisions. This opportunity for the presentation of complaints should always be open. Do not delay taking action on such matters whenever they are presented.

These suggestions, of course, are not offered as a patent remedy for all salary difficulties between an executive and his subordinates. They will not be of much help if the salary and promotion plan is not sound. On the other hand, if a valid plan has been established and if each executive will interpret this plan as his own and will maintain a frank relationship with his subordinates at all times on salary matters and progress status, much will have been done in the promotion of efficiency and happiness throughout the organization.

APPENDIX

Technique of Writing Class Specifications

(The following instructions for the preparation of specifications for any class of positions are reproduced below with the permission of The American Council on Education, 26 Jackson Place, Washington, D. C.)

These instructions are designed to show how the items of the specification can be developed and listed in a simple step-by-step manner. It will not be necessary to follow these steps in the exact order in which they are presented. The idea of being so explicit is to give a clear understanding of just what the items should contain to develop a good specification.

While the gathering of facts and moulding them into specification form is not to be done by the usual questionnaire method, self-questioning is recommended as an excellent means of accomplishing the desired results.

1. **The Things to Be Done.** Form the list of your specifications by continually asking the question "What do I do?" Then jot down on plain paper all the different things you do in two-word items, just as they occur to you. For instance:

File Contracts

2. **Essential Things.** A specification according to the definition should show the *essential things* done. Essential things are those you would naturally refer to in discussing your work with your employer or a fellow employee engaged in the same line of work. You know that they are familiar with the unimportant features of your work and you would not mention them. Now revise your list. Pick out and retain the essential items, and discard those which are unimportant. The objectives retained in the list must be essential

ones whether they be main or contributing. Only those which are plainly unimportant should be deleted. For instance:

Open file
Select index
File contracts
Close file

This listing includes some items of little or no importance.

File contracts is the essential thing done. Omit the others as unimportant.

3. Denote Action. Before going further it would be well to recall that it is the objectives of your position that you are listing. An objective requires action on your part in order that ultimately it might be accomplished. Therefore, the items of the specification should denote *action*. The proper method of doing this is by always beginning each item with a word which denotes the act of accomplishing an objective. For instance:

FILE Contracts

At this point a word of caution against beginning the item with a word denoting other than the act of accomplishing an objective is advisable. In order to make this clear let us say that you have been in your present assignment a relatively short time and have not as yet become familiar with all of its requirements. In that case you may be doing some of your work in an inexperienced manner; you may be practicing to do certain things still too difficult for you to accomplish satisfactorily or there may be other things you have not yet undertaken. If such is the case list all of the things you know of and denote action as though you are now doing them regardless of how well you are doing them, how hard you are trying to do them or how able you are to do them. Therefore you are to avoid beginning your items with words implying indirect action. For instance:

Good form
File contracts

Poor form
Endeavor to file contracts

4. Kinds of Things. The next step is to run over the items and enlarge each one into a three-word item by asking a second question—"What kind." That is "What *kind* of contracts." The result probably will be:

File Building contracts

5. Developing the Items. While the three-word items thus far developed are the foundation of the specifications they are in most cases too meager for practical use. Even one who is familiar with your work might be in doubt regarding the real meaning of some of the items. They should be expanded therefore with the idea of making them more descriptive or having them indicate any unusual or important features which are likely to be overlooked.

Proceed to develop the three-word items by continuing to ask questions of yourself. Inquire as to what descriptive information it would be well to add to each item to indicate any important or unusual features of the principal elements of the position, as follows:

a. Purpose. What is the purpose of this objective? Indicate purpose, thus:

Total ledger accounts *preparatory to balancing*.

b. Worker. What unusual or important qualification of the worker is necessary in the fulfillment of this item? Indicate qualification thus:

Give frequently requested numbers *from memory*.

c. Tool. What unusual, important, scientific, power- or labor-saving tool is used? Indicate tool, thus:

Prepare *adding machine* totals of payments.

d. Process. What next step does the accomplishing of this item lead to? Indicate process, thus:

Give *verbal report* immediately upon receipt of payments.

e. Production. Is a separate and distinct unit of work accomplished through this objective? Indicate unit, thus:

Sort *bill stubs* in numerical order.

f. Location. What is outstanding about the worker's location in achieving this objective? Indicate location, thus:

Secure new subscribers by *house to house* visits.

g. Other Individuals. Who will benefit by completing this item? Indicate other individuals, thus:

Make up monthly summaries for *bookkeeper*.

6. Correct Names. The use of incorrect names is often the root of misunderstanding or serious error. Go over each item of your specification and see that all materials, tools, operations, etc., have been referred to by their correct names. Examples of correct and incorrect names are:

Correct	Incorrect
Service order	Line order

7. Complete List. A complete list of objectives is important. Be sure you have all the *main* objectives and it will be comparatively easy to add the associated contributing objectives.

A further aid in developing a complete list is to take at least one month to complete the writing of your original specification. In this way you will be reminded by your work to list not only the things you are doing day after day but also those things you do once a week, once a month and occasionally during a longer period.

Speak with your fellow employees who are doing the same kind of work as you are. They probably will be able to suggest some items which you might otherwise overlook.

It may be that you have not been in your present assignment long enough to have become fully familiar with all of its features. If such is the case you are not in a position to make a complete list. Proceed by listing all the items of your work you have experienced thus far and request your immediate superior to supply those you have not yet encountered. In listing the things which you will be required to do later in your present assignment

you are reminded to denote action in wording the items, as though you were now doing the work.

8. Order of Listing. You have discovered in writing your specification thus far, that you have quite a number of objectives you are seeking to accomplish through your daily work. It was suggested earlier that you jot down the items just as they occur to you but it is highly desirable that they appear in the finished specification in some logical order. Proceed by first determining which items represent the *main* objectives. Then group the remaining items under each of these as your *essential contributing* objectives. Arrange the groups according to their relative importance, sequence of performance, or as directed. List the individual items of each group in a step-by-step order just as you do them in your work.

CHAPTER V

MEASUREMENT OF OFFICE OUTPUT

UNITS OF MEASUREMENT FOR OFFICE WORK

BY WALLACE CLARK, *Wallace Clark and Company*

Importance of Standards of Output. The purpose of measurement in offices is to get work done. Work must be expressed in measured quantities in order to know at any time how much has been done and how much remains to be done and it is upon this knowledge of the volume of work that the plans of the management for getting it done are mainly based.

Modern management has found that the most effective means of getting work done is to establish standards of output and to compare actual production with those standards.

There are several reasons for doing this:

1. In order to find out what office activities are moving too slowly or too fast, so that the causes may be investigated and the obstacles removed or the plans revised.

2. In order to provide a basis for payment by results. It is only a matter of fairness to pay high wages to those who do more than the average amount of work and this is not possible unless there is an accurate method of measuring the quantity of work done.

3. In order to judge the progress made by an individual or group by comparing current output with past records. Promotion depends primarily on progress and quantitative records provide a more dependable basis for judgment than general impressions.

4. In order to compare individuals with others or with a group to find out which ones are in need of training or instruction or possibly of being transferred to types of work for which they are better fitted.

When actual production of work is compared with standards for these four and other reasons, the result is a reduction in the cost of the work.

Quality Standards. Before the measuring and recording of any kind of office work is attempted it is necessary to establish quality standards and to provide for maintaining them. If such provision is not made, any attempt to increase the quantity of output will almost invariably result in the lowering of its quality.

The quality of office work is indicated in two ways: (1) accuracy; (2) appearance.

1. Errors can be measured and expressed in quantities and therefore definite standards of accuracy can be developed. Departures from these

standards are expressed in numbers of errors. These standards differ according to the policy of the company and according to the nature of the work. For instance, in preparing invoices to customers, the standard is absolute accuracy, but in securing monthly balances of controlling accounts, errors in cents are usually disregarded and in some companies, if differences do not amount to more than \$10.00, \$20.00 or \$50.00, the accuracy is considered satisfactory.

The important thing is to have the standard of accuracy definitely determined, written down, and clearly understood by those who are doing the work.

2. The appearance of work, that is, its neatness, legibility, etc. can seldom be measured and the standards are therefore expressed in written instructions, which are made as clear and definite as possible. The inspection of work and its comparison with these *standards of appearance* is therefore done by the application of trained judgment rather than by measurement.

As an example of the application of quality standards, we may take a letter which has been transcribed by a stenographer. It is inspected, possibly by the head stenographer, and its accuracy is measured by the number of errors in recording the words of the dictator, in grammar, in spelling, or in typing. Its general appearance, however, cannot be measured and the inspector applies her trained judgment, deciding that the letter either is or is not up to the quality standard which has been decided upon. She also decides what must be done to bring it up to the company's standard of appearance.

In manufacturing plants the responsibility for quality is not usually placed upon the line executive, but a separate organization of inspectors, which does not report to the foremen or superintendent, maintains the quality of the product. This practice, however, is seldom, if ever, applied to offices where department heads and their subordinate executives are held responsible for both the quality and quantity of work done by those under their control. It is therefore necessary for line executives to arrange for such inspection of office work as will assure the maintenance of quality standards both as to accuracy and appearance.

Units of Measurement. The first step toward measurement is to decide on the unit, that is, the individual thing which is to be used as a standard of measurement. Upon the proper selection of this unit largely depends the success of the measurement: it must be understandable by the average person and easy to apply or it is not likely to be used to the best advantage.

Whenever it is deemed worth while to measure and record the quantity of work done, it is invariably worth while to measure and record the errors. The unit of measurement of accuracy is therefore set down in this paper along with the unit of measurement of output, except in those cases where it is so obvious as not to be necessary.

Before units of measurement can be decided upon it is necessary to know what is to be measured. For our present purpose office work may be divided into four classes:

1. Handling papers.
2. Correspondence and typing.
3. Clerical and statistical.
4. Accounting

1. Handling Papers. The first class of work, handling papers, includes the handling of incoming and outgoing mail, departmental communications, messenger service, and the sorting, filing, and finding of papers. In general the unit of measurement here is a sheet of paper or several sheets fastened together and regarded as one letter or report.

In the handling of *incoming mail* in a *mailing department*, the units of measurement of output and of errors are as follows:

In the operation of slitting envelopes by machine or by hand the unit of output is one envelope and the unit to be used in measuring quality is the contents of one envelope which are cut or mutilated.

In taking papers from envelopes and date stamping them, the output is expressed in the number of letters or reports, and the quality is measured by the number of letters which are not date stamped.

In sorting papers the unit is again a letter or a report and the quality is reflected in the number of errors in sorting.

In the distribution of mail the unit is a station or desk to which mail is delivered and the quality is judged by the number of batches of mail delivered to wrong stations or desks.

In each of the above cases, except the last, the unit of measurement of output is a piece of paper. Before any standard can be set or any progress recorded the time element must be introduced. The amount of work done must be expressed in quantity and time; for example, the number of envelopes opened per minute, per hour, or per day.

In the handling of *outgoing mail*, the first operation is the collecting of papers from stations or desks. This work is measured in the number of trips and the number of stations or desks visited on each trip. Errors consist in variations from the schedule, that is, the failure of a messenger to stop at a station as directed in his time table.

In the sorting of outgoing mail, the unit of output is a letter or report and the quality is measured by errors in sorting.

In enclosing outgoing mail, where letters are checked before being placed in envelopes, the unit of output may be the number of envelopes, the errors being made up of letters enclosed in wrong envelopes and later returned from the recipients.

In stamping mail the unit is the number of envelopes and the errors consist of envelopes returned due to incorrect postage.

In handling incoming and outgoing telegrams and cables, the unit of output is the number of telegrams or cables and the errors consist of inaccurate records or delays in transmission.

In dispatching interdepartmental communications, the unit of measurement is the number of papers handled and the errors consist of mistakes in sorting.

In messenger service outside of the office, the unit of measurement is the number of trips to the various zones of a city, the quality of the work depending upon the time spent on the trips.

In a *filing department*, the output is measured usually in the number of papers sorted, placed in the file, or taken out of the file. Quality of filing is maintained by periodical inspection of the contents of files and the recording of papers misfiled.

2. Correspondence and Typing. Correspondence and typing include the dictation of letters, instructions or reports, the transcription of dictated matter, copying, duplicating, addressing, etc.

In the *dictation of letters* or reports the unit of measurement is the number of lines dictated, and the standard is expressed in lines dictated per minute. The quality can be maintained only by a periodical inspection of outgoing letters.

In comparing the work of two dictators allowance must be made for the relative difficulty of the matters handled. However, delays in dictation are not due so much to the difficulty of the subject as to the lack of preparation and to interruptions due to telephone calls or conversations.

In *transcribing matter* from dictation or from a dictating machine and in copying, output is measured preferably in lines.

In order to use this unit it is necessary to standardize the length of line. (This is usually six inches.) It is then easy to measure the number of lines by laying on the typewritten page a scale showing on one side the number of lines for single spacing, and on the other, double spacing. The standard for transcription is therefore expressed in a number of lines per minute. This standard differs according to the style of type, that is, the standard for lines of pica type is greater than for elite type. It also varies according to the difficulty of the matter dictated.

There are other units of measurement for typewriting work, one of which is square inches. This, however, is unfamiliar to most people, because they have never seen a square inch of typed matter. A measuring scale for square inches must be as large as the sheet of typewritten matter and is more awkward to apply than the scale showing the number of lines.

Typing is also measured by cyclometers, which record the number of strokes on the typewriter. The principal disadvantage of the cyclometer is that it records incorrect work as well as correct, and there is no easy way to make the necessary deduction due to errors. When the unit of measurement is lines or square inches, the quality is assured by the inspection of all outgoing letters, either by the head stenographer or by the dictators. Work which is not up to the company's standard is rewritten and only typed matter which passes inspection is measured and recorded.

Although transcription from dictation and from dictating machines and copying are all measured in lines, the standards expressed in lines per minute, differ for each kind of work.

In the *typing of orders or invoices*, whether done on standard typewriters or on billing or accounting machines, the output is usually measured in long or short orders or invoices.

A careful analysis of the number of items per invoice is necessary in order to determine a standard. The quality in typing figures should be maintained by careful inspection or by checking on adding machines.

In the *cutting of stencils* the unit is the standard line, unless the stencils are confined to names and addresses, when the unit is a name.

In *addressograph* work the making of new plates is measured in number of names. The running off or printing is also measured in number of names.

The standard may be the number of envelopes addressed per hour, the number of names listed on a payroll per hour, et cetera.

In *multigraph* work the unit for composition is the number of lines set up and for impressions the number of sheets printed.

In the use of "Ditto" or other types of *duplicating machines*, the output is measured in a number of impressions, the quality being reflected in the number of illegible or spoiled sheets.

In *automatic typewriting* the unit is the typed line. The standard, however, is usually expressed in the number of letters, after having taken into consideration the number of lines per letter.

3. Clerical and Statistical. Clerical and statistical work consists in general of transferring information from one set of forms to another set or to a report. This usually entails a rearrangement or tabulation of information, together with the drawing off of totals, averages, percentages, etc., and is done either by hand or by the use of office appliances. It is difficult to differentiate between clerical and statistical work, but without being too precise we may include in statistics the handling of figures and in clerical work the transferring of information which consists partly of figures and partly of other information.

In an *order department* the unit for measuring output is an order. If there are different kinds of orders on which the amount of clerical work varies, the standards will vary according to the type of order.

The measuring of errors differs from each operation. In visiting or checking the accuracy of orders, the errors consist of mistakes overlooked. In entering orders on an index, the errors may be in copying or in omissions of information. In extending prices, errors are made up of mistakes in extensions. In checking items filled or shipped, the quality of the work is measured in items overlooked.

In a *traffic department* the output is measured in:

Number of shipments routed.

Freight bills checked, etc.

In a *purchasing department* the units of measurement are:

Requests for quotations sent out.

Purchase orders placed.

Purchase orders filled.

Invoices approved for payment, etc.

In a *storeskeeping department* which keeps a live inventory or balance of stores, work is measured in the number of entries made on balance cards or in the number of forms from which postings are taken.

In the drawing off of reports or in miscellaneous clerical work, output is measured either in the number of forms handled or in the number of reports completed. In a few cases the number of items transferred represents the output.

In the setting of standards the number of items per form or report must be taken into consideration. The quality is reflected in the number of errors in posting, in extensions or in footings or in the number of items omitted.

Clerks frequently have to sort or file papers or do other work not included here under clerical, but the four divisions mentioned here are of office work rather than workers.

4. Accounting. Accounting, the fourth and last class of office work, consists principally of posting information in dollars and cents from one set of records to another, in totaling entries and proving their accuracy and, finally, in drawing off from these records certain reports which show the financial condition of the business.

In posting debits and credits, the amount of work is expressed in items posted. The accuracy is measured in mistakes in postings.

Standards for work of this kind are usually expressed as a number of items posted per hour.

In auditing invoices the unit of measurement is the invoice and the measure of accuracy is the number of mistakes in invoices which are overlooked.

In the operation of adding or calculating machines the work is measured in the number of forms or folios handled and the errors obviously consist of figures incorrectly transferred to the machines.

When accounting is done on tabulating machines work is measured in:

- Number of forms coded.
- Number of forms punched.
- Number of punch cards checked.
- Number of cards sorted and filed.
- Number of cards tabulated, etc.

Supervision of Office Work. The object of supervision is to get work done accurately, on time and at a reasonable cost. All of the characteristics which a supervisor needs are brought into play in the execution of his task of getting work done. By making a special drive any supervisor, no matter how poor, can make a good record for one day and even for a few weeks, but if over a long period of time he gets the work under his charge done accurately, on time and at a reasonable cost, we must acknowledge that he is a good supervisor.

Since it is the responsibility of the supervisor to get work done, the units of measurement of his work are the same as for the work supervised.

In a stenographic department as a whole the unit of measurement is the line transcribed or typed. The quality is measured in the number of errors which go out of the department.

A standard set for a head stenographer differs from that of a stenographer. The latter is judged according to the number of lines per minute—she has no control over the assignment of work or the amount of time she spends waiting for work. The head stenographer, however, is judged not only by the rate at which her subordinates do their work, but by the assignment of work. Her standard is therefore expressed in the number of lines transcribed and typed per day and in the number of lines left over at the end of the day.

The work of other department heads is similarly expressed in an overall measure rather than in detailed operations. For instance:

Number of orders passed through and left over.

Number of policies handled and left over.

Number of transactions handled and left over.

Much of the work which has been mentioned might be *graded*: for instance, a supervisor might be graded as to initiative, loyalty, cooperation, responsibility, etc. Also quality might well be graded, particularly as to appearance; for instance, a head stenographer might have a form of letter in mind the appearance of which she would arbitrarily value at 100, and when inspecting a particular letter she might compare it with her ideal and value it at 80. In this paper we are not concerned with grading, which is judgment or opinion expressed in figures, but with the quantitative measurement of work. It is the general practice to make use of grading only where it is not possible to secure accurate measurement.

It may be said that it is not worth while to measure and record some of the comparatively simple operations which have been enumerated here. It is undoubtedly true that in a small office which receives a few hundred letters per day, it is not worth while to measure and record the operations listed here under a mailing department, but in a mail order house which receives 100,000 letters per day, it is well worth while. The volume of work is the principal factor in deciding whether or not it is advisable to measure and record office work.

This paper does not attempt to urge the measurement of work or to present any formula by which one can tell whether or not it will be profitable to measure any particular activity. The purpose is rather to enumerate some of the units of measurement which are accurate and practical, so that when it is considered desirable to measure any specific kind of office work, it will be easy to make the first step, which is to decide on the unit of measurement.

THE TECHNIQUE OF DETERMINING THE "ONE BEST WAY"¹

By B. EUGENIA LIES, *Director of Planning, R. H. Macy & Company, Inc.*

The purpose of determining the one best way of doing work is, as Gilbreth has said, in "Applied Motion Study" (p. 41), to eliminate waste due to "needless, ill-directed, and ineffective motions and their resulting unnecessary fatigue, and the transformation of such ill-directed and ineffective motions into effective activity." Such effective activity results in increased production, as measured by the unit of work or unit of measurement.

In order to illustrate the method of determining the one best way, we have selected a very simple operation which occurs in the record room; that is, the operation of posting errors on the Record card. These error records include those premiums or errors made by salesclerks which are detected by cashiers and merchandise checkers (that is, wrappers), late slips which record tardiness, blunder reports covering errors made in writing sales-

¹ This paper was read before the Office Executives Conference of the American Management Association, February, 1926.

checks, and others. The error records are posted on the inside of the record card.

We have chosen this simple operation as an illustration in order not to obscure the description of the technique by a complicated operation. The method, however, may be used equally well for a complex system. It consists of

1. Analyzing present methods.
2. Selecting the best elements of those methods or determining simpler, better and more direct methods, if possible.
3. Synthesizing the best elements into the one best way.

The process chart shown in Fig. 1 is the instrument used for analyzing the operation. It shows in a graphic way the detail of each step and every variation which may occur in each step of a process. The sequence of each step is shown in the chart both by the number given to the operation and by the location on the chart. The steps are shown following each other in the order in which they occur. If there are variations, each possibility is shown as a different section breaking off from the main line.

The nature of the steps is indicated by the symbols. For instance, the large circle indicates an operation, or something done; a small circle indicates movement; a square indicates inspection for quantity, and a diamond, inspection for quality.

After a process chart is made it is possible to see easily what steps are unnecessary. Also, it is possible to see what effect the elimination of one step will have on the rest of the process. That is, the process chart is a means

PROCESS CHART OF HAND POSTING OF ERRORS ON EMPLOYEES RECORD CARD

1. Of recording present practice in

FIG. 1.—Process chart used for analyzing the operation.

2. Of studying that practice step by step in order to determine the value of each step in relation to the rest of the operation.
3. Of determining and showing changes made in the operation.
4. Of recording, finally, standard practice.

Figure 1 shows the process chart of posting of errors on the record card. As the operation was being done at the beginning of our study, it involved twenty-one different steps. Eight of these steps have been eliminated and one has been changed.

The steps eliminated involved the use of pen and ink for posting and the resulting blotting of the entry. They were eliminated by substituting colored pencil for posting. The step which was changed was this: Originally the left hand held the cards back while the right hand posted; now the right hand posts and holds the cards back at the same time, while the left hand is free to turn the slips from which the errors are being posted.

These changes are clearly shown in a motion picture which was taken of the operation in order to analyze the method and motions in great detail and to record time. The film is of particular value in recording quick motions which are too fast to be caught by sight, but which by the motion film can be recorded accurately and then projected as slowly as desired for studying in detail. That is, the film presents a permanent record for minute analysis. Moreover, it is an errorless record which will show the action to any observer at any time in exactly the way it occurred. It actually records the motions and the method so that a survey of the film presents the material to everyone in the same way. After the analyses have been made and improvements installed in the equipment, in the method, and in the motions; this is, after a standard method is in practice, films are also taken and form a permanent record of the standard method. These are invaluable not only as a record, but also as a means of training, etc.

In selecting the workers who are to be filmed, it is desirable to choose the operators whose methods obviously have some elements of particular interest. This does not mean that the operator is always the quickest, or that his method is entirely good, but rather that some phase of his method is particularly good.

The pictures are taken at the usual work place or in the laboratory equipped like the usual work place, showing the usual working methods. The Gilbreth clock makes it possible to obtain the time involved in each part of the operation. This clock shows the division of time in one two-thousandths of a minute so that the time analysis is very small. Frequently a cross-sectioned background screen is used by which the distance of particular motions can be measured.

When inserting cards, after posting, in the vertical file the worker has considerable trouble in locating the proper place for inserting the cards. This searching obviously takes too long and can be reduced by the installation of a more complete index.

Since posting the amount of commissions on the sales clerks' cards is a permanent record and must be put into rather small boxes on the record card, it is necessary to use ink. The moving picture showed that the operator was using, very inefficiently, a pen and inkwell. The use of a fountain pen

would be more desirable. It was so apparent that the operator's left hand was idle a large portion of the time. It was possible to coordinate the motions of the two hands better when the left hand was used more for finding the card on which the next posting was to be made.

The picture of posting errors as recorded on premium slips showed that the arrangement of the work was obviously bad, in that the premium slips from which the data were being posted were kept on top of the file. This meant that the operator's hand moved a long distance from the file drawer to the pile of slips. The equipment also needed improvement. For instance, the employee was standing and bending over the tray. Much fatigue would be eliminated if she were seated at her work. She was also using pen and

FIG. 2.—Wheel of motion showing the complementary motions, also identified in practice by colors on Therblig chart.

ink which meant blotting the entries, as well as delay in dipping the pen into the ink. Also, there was evident delay because the right hand was doing too much of the work; that is, it was used for finding the card on which the posting was to be made, for writing the information and for blotting the entry.

A later picture showed the posting operation with some improvements. In the first place the arrangement was improved. The work ahead was put on a tray at the side of the drawer so that the distance between the work ahead and the cards on which the posting is to be made was decreased. The operator was seated and was posting with a crayon pencil instead of with pen and ink.

When the work place is arranged in the standard fashion the motions of the hands have been greatly decreased; that is, the right hand is used for finding the card and for holding the cards back, as well as for posting, while

the left hand turns over each premium slip as it is posted. The motions have been reduced so that the operator is reaching a minimum distance and is making as few motions as possible.

As stated above one advantage of taking a film is that the motions can be analyzed in detail. This is done on an analysis sheet and shows the period of time each motion takes. In this connection we should explain that the operation is analyzed into elements of motions or therbligs. These elements are minute divisions of motions, such as grasping, transporting loaded, etc.

As shown in the therblig chart¹ the seventeen elements of motion or therbligs are: Search, find, select, grasp, transport loaded, position, assemble, use, disassemble, inspect, preposition for next operation, release load, transport empty, rest for overcoming fatigue, unavoidable delay, avoidable delay, plan.

This chart also shows the symbols which are used for the elements and the colors which are assigned to them. Figure 2 shows the wheel of motions, illustrating the complementary motions; transporting loaded, for instance, is opposite transporting empty; releasing load is opposite grasping; assembling is opposite disassembling, etc. The complementary motions are easily identified because different shades of the same color are used for the complementary motions. Transport loaded is shown by dark green, and transport empty by olive green. The complete operation is analyzed into these fundamental elements of motion on the analysis sheet shown in Fig. 3.

This analysis is then shown in a visible form on a simultaneous motion cycle chart (which is called "simo chart" for convenience). See Fig. 4. This chart is made on cross-sectioned chart paper, with the time element shown by the vertical divisions, each division = $1/2,000$ th of a minute, and the description of the motion and the different numbers of the body used in each motion are shown horizontally. Here the analysis of the motion is particularly evident because a different color is used for each element of motion or therblig. At a glance, therefore, one can see the duration of each element and the duplication of each element. For instance, in the simo chart, which was made of the insertion of the card in the vertical file the enormous amount of time spent in searching was very evident. Thus, the simo chart shows quickly the elements of motion involved in the operation and the length of each element of motion.

One Best Way. By studying and comparing the simo charts, it is possible to discover which are the essential elements of motion in the operation, which are the shortest elements of motion, and which elements are taking a large part of the total time and should therefore be studied for possible elimination or shortening of the system involved. For example, all instances where avoidable delay occurs, should be carefully scrutinized and eliminated, if possible. This is particularly true when one hand is being delayed or is holding while the other is occupied. When this searching analysis of each simo chart is completed, the essential and shortest elements of motion are put together into the one best way. The one best way, as thus constructed, is established as the standard method of performing the operation.

¹ See p. 638

FIG. 4 "Simo Chart" giving the analysis into fundamental elements of motion in visible form

In order to introduce the standard procedure officially, a standing order is prepared and is issued by the general manager's office, authorizing the department manager to install the standard procedure and placing upon him the responsibility for maintaining the standard procedure. That is, no changes in the procedure can be made without notifying the assistant general manager who is responsible for that department. If a suggested change is found upon investigation to be desirable, the standing order is revised. Thus, an authoritative statement of each procedure is issued and serves as a means of installing the procedure and of maintaining it.

An instruction card is also prepared, explaining in detail the exact method of performing each phase of the procedure outlined in the standing order. The instruction card serves as a means of instructing the individual employee and also as a standard against which the work of the individual employee may be measured.

We have thus shown the details of the method which we use in establishing the one best way, that is,

1. Analyzing the present procedure, methods, and motions.
2. Standardizing the surrounding, the equipment, the tools, and the motions.
3. Maintaining the standard conditions and methods by means of the standing order and the instruction card.

The subsequent steps to the establishment of the standard include, on the basis of the one best way which has already been established:

1. Determining a standard day's work, and
2. Developing a bonus plan for providing incentive and for compensating the employee on the basis of actual production.

These steps are possible after the best methods have been established and a unit of work determined.

DETERMINATION OF WORK UNITS FOR OFFICE MACHINES

By I. O. ROYSE, *Manager, Office Production, Ralston Purina Co., Inc.*

Office machines are being installed on the theory that they will reduce clerical work and prevent an increase of the office pay roll. It is apparent that work may be done faster with proper machinery than it can be done manually. If, however, the clerks using machinery do not utilize the time saved the result is an actual loss to the institution. It follows that it is of paramount importance that production be measured as the means the office executive has for justifying the purchase of machines.

In addition, measurement of work assures the office executive of:

1. Knowledge of clerical help necessary.
2. Control and scheduling of work.
3. Rating of workers and determining a suitable reward for efficient work.
4. Getting the work done.

A unit which will accurately portray the progress made on a machine during a definite period is necessary for measurement. The determination of significant work units is the problem. In measuring work on office machines, certain factors vary so that any one of them may affect production on a given operation, namely:

1. Speed of machine.
2. Size and quality of material.
3. Individual differences of the operator.

The most effective speed of the machine, *i.e.*, the greatest speed at which the machine may be run without impairing its efficiency, will certainly affect production. That speed must be determined and checked frequently to insure standard conditions. Mechanical changes on any machine should be allowed only after they are proven to be beneficial. In that case all machines in the bank should be similarly changed. The size and quality of material—especially on duplicating machines (multigraph, mimeograph, etc.)—will also affect output.

The ability of the operator to do certain kinds of work well is the object of much consideration. Certain specific abilities are required in some operations and not in others. For example, a person operating successfully a multigraph machine can not necessarily operate a billing machine with the same proficiency. Specific psychological tests have been, and are being devised as an aid in classifying operators. With the use of these tests it is possible to place the worker with some degree of accuracy in the position where she is most likely to succeed.

The actual steps and procedure used in this case to determine the work units for office machines are given here:

- A. Preliminary steps.
 1. Analysis of job:
 - a. Material.
 - b. Equipment.
 - c. Conditions.
 - d. Methods.
 2. Standardization.
 3. Selection of and obtaining proper attitude of workers to be studied.
 4. Motion study.
 5. Time study (determine net production per hour).
- B. Recording production.
 1. Obtain necessary information:
 - a. Identification.
 1. Department.
 2. Operator.
 3. Machine and operation (sketch arrangement).
 - b. Production.
- C. Final analysis and conclusions:
 1. Consider individual differences of operators.
 2. How will errors be taken care of?
 3. Allowances:
 - a. Unavoidable delays.
 - b. Personal time.

- c. Fatigue.
- d. Irregularities.
- 4. Determination of work unit.
- 5. Set up trial production standards.
- 6. Check information for accuracy.
- 7. Provide for maintenance of quality.
- 8. Determine what records will be needed.
- D. Verify conclusions by further study and recording.

Figures Illustrative Only. *The figures in this paper are selected for illustration only and cannot be used safely for establishing standards.*

Graphotype. The work consists of embossing one-piece metal address plates on type G 3-44 graphotypes. The work must reach each machine in a standard condition and similar equipment must be available. After the necessary changes are made for standard and desirable conditions the entire cycle of work is studied and divided into definite elements as follows:

	Minutes
1. The operator is given a job ticket, list of names and a time ticket "rung in" for her.	1 00
2. List is placed in the copy holder and adjusted.30
3. A tray of blank address plates and an empty tray are placed in position on the right table of the graphotype machine (blank address plates must be next to operator)	1 15
4. The operator places a working supply of address plates to the left center of the machine table.08
5. With the list as a guide, the operator embosses the address plates placing them to the right center of the machine table and later, when a sufficient number has been accumulated, to the empty tray on the right table (see 3 above)90
6. As each name is embossed the list holder is changed to index the next name01
7. If more than one tray of address plates is embossed, additional ones may be procured from shelves directly behind the operator.01
8. The tray of embossed address plates and the list are returned to the supervisor and the time ticket is "rung out".	2 55

Study of the individual elements shows that four of them (1, 2, 3 and 8) are impractical for measuring the work because of the variation in the number of names on each list (job). From one of the other four elements (4, 5, 6 and 7), the basis for the work unit must be selected. Four, six and seven depend entirely upon five and may vary, hence the criterion for the unit is one address plate embossed. It would obviously be incorrect to measure the work on the graphotype machine by using the net time for embossing, i.e., number of plates embossed per hour. When the overall time is considered, this number varies with the interruptions due to job changes and necessary allowances. The unit determined must include allowances for these variables.

A study of embossing shows that 60 address plates per hour may be handled by a certain girl. Information obtained from a study of the other elements shows that a job change occurs on the average of once every 60 plates. The total time for 1, 2, 3, and 8 is five minutes. That leaves 55 minutes out of each hour. Adding 4, 6, and 7, and considering the number of plates embossed in

55 minutes means an additional allowance of 5.5 minutes. With no personal allowance or allowance for fatigue it would be possible to emboss 49.5, or say 50, plates per hour when all incidental handling time is included. The actual allowance made depends upon the judgment of the time study man. In this case about 12 per cent was allowed reducing the 50 per hour to 44. It is apparent that the figure 44 not only represents the plates embossed in an hour but certain handling time and all other allowances. The unit of work therefore involves more than the embossing of one plate. The measure of the output of graphotype machines may be made in terms of this unit, 44 of which is the standard for an hour's work.

The total production shown on the time tickets for the day should check with the total production on the finished jobs. The work is inspected and each operator is required to correct her mistakes on her own productive time. There is some variation in the number of strokes per address plate but over a period of time it is so little that an average is found practical (fifty-three strokes is found to be the average).

Addressograph. The cycle of work at the addressograph machines, model F-1, consists of seven elements:

- 1 The operator receives the job ticket, material to address and a time ticket "rung in"33 minutes
 2. The plates specified are taken from the file..... .75 minutes
 3. Plates are placed in the machine.62 minutes
 4. The operator takes a working supply of the material to be addressed and places it face down on the left side of the machine table..... .15 minutes
 5. The operator feeds the machine with left hand, material face down, and removes and turns it over with the right hand. A foot lever is used to regulate the speed of the machine..... 1,200 per hour
- NOTE. A helper inspects the work for defects. If necessary it is immediately returned to the operator who adjusts machine and reruns defective work, or helper makes the corrections by hand.
6. If other trays of plates are to be used for the same job the operator returns used plates to the filing cabinet and repeats operations 2 and 3..... 65, about .001 per address plate
 7. When the job has been completed the time ticket is rung out..... .30 minutes

The unit finally determined is based upon element 5. Study of this element shows that 1,200 pieces per hour is a basic average on a straight run. It also shows that there is approximately 1 job change requiring 2.5 minutes to each 150 pieces addressed. In 1 hour 6 jobs of 150 can be completed. An allowance of 12½ per cent is made on this operation reducing the expected output from 900 to 800 units per hour.

Flexotype. Hand composition and distribution of loose type on letter-heads for multigraph work is done on the flexotype machines. Composition and distribution were studied separately. Cycle of elements of the flexotype operation follows:

A. Composition.

1. The operator takes job ticket and master copy from the in-basket and separates them. From the job ticket the information required for keeping record of the work may be obtained.

2. Time ticket is "rung in."

3. Margin alignment and proper spacing is arranged on the segment by referring to the master copy.

4. The master copy is placed in the copy holder.

5. With the flexotype-setter directly in front of her and the segment on her left, the operator releases or "picks" a line of characters from the channel of the machine banks and transfers them to the channel of the composing fork.

6. After each line is transferred to the fork it is set on the segment.

7. The type is spaced for indentation and "frozen" in place on the segment by the use of lock-line clips.

8. The completed segment, together with the job ticket and master copy, is placed on the desk of the girl who makes proofs of all work composed.

9. The operator "rings out" the time ticket.

B. Distribution.

1. After the job has been run, segment, master copy, and job ticket are returned to the operator.

2. The operator rings in a job ticket to cover distribution time.

3. The type is taken, line by line, from the segment onto the fork and distributed in the flexotype-setter.

4. When complete the operator rings out the time ticket.

When the proof reader discovers any errors the segment is returned to the original compositor who makes the correction on production time. The ratio of composition to distribution is found to be about 7 to 9. As it is necessary to distribute all type composed it is found that a single unit can be determined which will accurately measure the whole operation. The type set may not be distributed for a week or more, therefore it is impossible to give the operators credit for both composition and distribution at the time the letter is composed. The measurement determined, based on pieces of type set, is 880 units per hour.

An extra proof of the letter is made and the count is estimated on the line basis. This count is copied on the time ticket attached to the proof. After the type is frozen on the segment, proofed and okehed, the segment, together with the material to be printed, is placed on a table behind the multigraph machine operator. That brings the job to the multigraph operator in the same condition each time.

Multigraph. Manual, automatic, and Davidson Automatic feeds are used which make it necessary to have three distinct units of measurement on multigraph work. The units are similar, varying only on account of time allowed for adjustments, constancy of feeding, fatigue, etc., as well as increased speeds in the case of automatic feeding. The elements for the cycle of the manual fed multigraph work are:

1. The machine is inked (as a rule a machine is inked only once a day), the segment placed upon it, a trial sheet run through and compared with the master copy to get proper placement. If adjustments are necessary they are made and a working quantity of material is placed upon the machine "table."

NOTE. If anything other than an imprint job the copy must be okehed by the supervisor before beginning the job.

2. The calculagraph ticket is rung in.

3. The operator picks up the material with her left hand, places it on the paper table, and feeds the machine with her right hand (this element would be changed for automatic feeding).

4. When more material is needed it is obtained from the table directly behind the operator.

5. When the job is complete the operator cleans the type on the segment, removes the segment from the machine, places it upon the table directly behind her and picks up the next segment with job ticket and master copy.

NOTE. Stopping one job and starting another, as indicated, is recognized as a change for which a special allowance is made in terms of the multigraph unit.

6. When job is complete the ticket is rung out.

A machine helper and lookup girls supply the material as well as inspect the work done and lay it upon the drying racks. If a machine breaks down, or something occurs which is beyond the control of the operator, she "rings out" her time ticket and "rings in" a general time ticket.

The unit for multigraph work is based upon the number of pieces fed. Automatic and Davidson feed units differ from hand feed units in proportion to the variation in element 3, as well as other variables. In this particular operation we must consider special work which does not occur regularly with each job. Example: (1) If proof is taken by operator an added allowance in terms of the multigraph unit is made—allowance is equivalent to average time required for this additional work. (2) Change allowances are also made to compensate the operator who runs a number of small jobs instead of long jobs. These allowances are determined by the time required to make the change. To illustrate, if hand feeding can be done at the rate of 1,000 per hour, the allowance made for the change mentioned in element 5 would be $8\frac{1}{3}$ units when the average change requires one-half minute. $\frac{(1,000 \times .5)}{60}$.

Mimeograph. The unit for measuring mimeograph work is also based on the number of pieces run. The complete cycle of 15 elements enters into the determination of the production requirement of 786 units per hour. While a quantity of slip sheeting is done, the operator can do it without materially decreasing the speed.

Ditto. The ditto machines are used on two distinct classes of work. In the one department the machine is used to duplicate orders. The number of copies required varies from about 10 to 22, the average being 12 copies per master copy. The small number of copies per job means a greater number of job changes and less time every hour in which to duplicate. An allowance for separating copies after duplication is required. The unit per hour is based upon the single duplicated sheet. The other ditto machines present an entirely different problem. Two distinct classes of jobs are handled on them. One class is composed of long jobs requiring no extra handling, while the other class consists of special semi-weekly reports requiring few copies per master sheet. The work is divided and different units determined for each class. On the short job class the work unit must provide for more allowance time

on account of the increased number of job changes for a given number of duplicated sheets. The nucleus for the unit in both cases is the single duplicated sheet.

The last two operations to be discussed will present two entirely different problems. One is measurement of work on the Hooven automatic typewriters, the other is measurement of work on the Burroughs-Moon-Hopkins billing machines.

Hooven Typewriters. Measurement of work on the automatic typewriters is done in the following manner: This typewriter operates automatically by means of a "stencil" cut on a separate machine. The completed stencil resembles a player piano roll, which is placed on the typewriter and turns over a drum or feed wheel. Little teeth drop into the holes made in the stencil forcing that particular type bar to print. There are fifty channels in this feed wheel, which is regulated to turn thirteen and one-half times per minute. If it were possible to have a stroke for every channel, 675 strokes could be made every minute; however, the stencil cannot be cut to give this result. A certain allowance must be made on the stencil for carriage returns, shifts and other adjustments peculiar to the machine. A detailed study of the stencils cut shows that the efficiency of the machines are reduced approximately 18 per cent by using the necessary spacing. That decreases the possible machine speed to 550 strokes per minute.

As many as five machines are operated by one girl at a time. The problem is to determine the measurement of the production when more than one machine is operated at the same time. A time allowance of 12 per cent for fatigue, delays, putting paper in machine, etc., leaves only seven possible hours running time per eight-hour working day. To facilitate the measurement of work done a cyclometer is used, which registers ten strokes per cyclometer unit reading. The output of one machine is calculated to be 29,932 strokes per hour. Study of the work on more than one machine shows that the efficiency of the machines is reduced as each machine is added. The following table shows the reduction:

Machines	Percentage Efficient
1	100
2	81
3	56
4	50
5	47½

Additional allowances are made in terms of this cyclometer unit for the following:

1. Changing stencils (96 units).
2. Address letter manually (48 units).
3. Allowances per envelope addressed on a regular typewriter (12 units).

Billing Machine. At first it seems impossible to measure the work of the Burroughs-Moon-Hopkins biller. Seven different invoices are used and because of different methods of shipment such as pool cars, stop-over cars, etc., numerous irregularities frequently occur. Copies of invoices and records

of the various kinds were kept for a period of three months. The measurement was further complicated because girls doing the work for different sales territories had entirely different kinds of invoices to write. The amount of typing on each invoice varies considerably. Five distinct groups of invoices were found which showed such a degree of similarity that certain parts of the invoices for each group could be written in approximately the same amount of time. However, the criterion for measurement could not be based upon that time, as the overall time for writing the invoices varied in proportion to the number of commodities listed on each. Further study showed the time for writing the name of commodities on each group of invoices to be practically equal. In order to determine the value of that fact as a basis for measurement, it was decided to divide the billing operation into its elements. The resulting cycle was found:

1. "Ring in" time ticket when starting invoice.
2. Take order (with correspondence attached) from in basket.
3. Unclip and spread out on machine table.
4. Take invoice from cabinet with left hand, place against left paper guide, and roll into place with right hand.
5. Type heading.
6. Type shipping instructions.
7. List commodities and make extensions.
8. Turn invoice out with right hand, push back into roll with left and turn roll with right, bring back of invoice forward.
9. Prove extensions and total.
10. Prove weights and total.
11. Take invoice out of machine.
12. Assemble and clip together.
13. Mark production report (show kind of invoice written and number of commodities).
14. Stamp invoice with credit stamp.
15. Ring out ticket unless there is more work waiting in which case the cycle should be repeated.

Every order is carefully inspected and all irregularities cleared, making it possible to deliver them to the biller ready to write. After the invoice has been written it is carefully checked for errors. Errors made by the biller are corrected by her on productive time. Other irregularities overlooked by the clearer are in most cases corrected by rewriting. The biller gets credit for this rewriting.

Time study shows that each element in the cycle, with the exception of those which vary with the number of commodities listed, can be typed in approximately the same time. Most of the elements in the cycle are affected by the number of commodities listed, however. The more one studies this operation the more apparent it becomes that no one element will furnish a criterion of the output. If some element, most indicative of the quantity of work done, can be used as the unit and the other variables evaluated in terms of that unit, certainly the amount of work done on an invoice could be measured.

Let us, for example, say that we shall take invoice type "A." Time study has shown us that the following points would be allowed to bill the invoices:

	Units
1. Time allowed per sketch.....	20.1
2. Time allowed per item.....	8.7
3. Typing time allowed per cyclometer unit.....	1.2

Therefore, if invoice "A" has ten items and twenty typing units the allowed points will be 131.1.

Success or failure in the measurement of any work depends upon a clear concept of the best theory and practice in the application of analysis to that work. It is impossible to definitely determine an accurate and fair work unit unless procedure similar to that given herein is followed. On much machine

FIG. 1.—Results obtained by installation of wage incentive for office workers Ralston Purina Company, St. Louis, Mo.

work the criterion for measurement is the number of pieces handled. The actual unit of measurement for each machine, however, not only includes the handling of the piece of material or accomplishing an arbitrary amount of work but it is the work plus an allowance sufficient to cover known and possible unforeseen delays.

The results of the installation of wage incentive plans for our office workers have been very gratifying, indeed. Considering 100 per cent to be the unit cost of production on an office operation at the time the incentive plan was put into effect a direct ratio with the present cost has been calculated. In only one of fourteen operations has the unit cost increased any and in that

instance the increase was 1 per cent. In the thirteen other operations the present unit cost ranges from 21 per cent to 89 per cent of what it formerly was (see Fig. 1).

Using as 100 per cent the compensation that was paid the workers when the various operations were put upon an incentive basis a direct ratio between original and present salary has been determined. In every single instance the wage plus bonus that is now being paid the workers has shown a remarkable increase over what the pay formerly was. The smallest increase in remuneration was 10 per cent, in an operation standardized only two years ago as compared with other operations standardized seven years or more. Other operations have shown increases up to 110 per cent over what the pay was before the inauguration of the incentive plans. Three of the fourteen operations show better than a 100 per cent increase while six have shown an increase of 80 per cent or more.

MEASURING OFFICE OUTPUT¹

By JOHN MITCHELL, *Associate Director of Staff, H. A. Hopf and Company*

Office output has a large number of variables that affect it. Not only is the nature of the work different, but the method of doing it varies between industries, companies within an industry and even between offices of the same company. To make the problem more difficult, the titles used for office jobs may be the same in half a dozen concerns, but the duties may be all different. To add to these difficulties, we must consider the human element with all its frailties.

The scientist in approaching a complex problem of this nature endeavors to resolve it into simple terms. He then takes each term, analyzes it carefully and lists the elements which he finds in it. He then defines each element and classifies it. From combinations of these elements he works out a conclusion to the particular problem and also other related problems.

Units of Measurement. In the same scientific manner we have resolved office work into simple terms such as, billing, typing, transcribing from dictating machines, key-punch and tabulating work, etc. The customary nomenclature used may be the same in all companies, but a brief analysis will show that there is a real difference in the work performed. For example, billing is a common term, but the work performed under that title will vary considerably as between a manufacturing and a merchandising concern. Altogether different from both will be the billing work which is performed in a public utility.

One may readily see that with such a wide variation it would be difficult to compile any single set of statistics that would be useful to these three types of companies. We are therefore compelled to seek a more elemental unit than the document which is called a bill. The same condition is true in

¹ This study was made by Mr. Mitchell as chairman of the committee on measuring office output of the American Management Association and presented in the *Office Executives Series, Bulletin 29 and 35.*

typewriting. If one asks a dozen companies to give a record of the output of their typists, he will find that it varies from 3,000 to 9,000 lines a week. When he analyzes the returns he will find that a line may be six or eight inches. Some companies make certain allowances for the address, salutation, and complimentary closing, and extra carbon copies on the basis of lines. Here again one must determine an element which is common to all typewriting for the purpose of making a standard. This element is the tap of the typewriter.

The Operating Cycle. When units of work have been established the job is ready for measuring. Determination of which motions of an operating cycle are to be measured should be reached after consideration of the cost of such measurement as compared with the probable savings. In the majority of cases, in order to secure satisfactory results, at least the following portions of the operating cycle should be measured: (1) get-ready time; (2) time to do the operation or work; (3) clean-up time. Every job can be broken up into these three steps. The second step will vary directly with the volume of work while the other two will remain fairly constant.

The number of studies to be made before arriving at a standard time should depend upon the number of operators and volume of work involved. At least twenty should be made for each type and variation within the type of work.

Procedures and Time-study Sheets. The following procedures and time study sheets applied to specific types of office machines have been used successfully and provide a basis for designing similar forms for application to other office work.

PROCEDURE FOR MEASURING OUTPUT OF TYPISTS AND OPERATORS USING TRANSCRIBING MACHINES

Name

Date

Type of Business

1. Name and maker of machine (typewriter)
(Name and maker of transcribing machine)
2. Model or style number of typewriter
Model number of transcribing machine
3. Are machines in constant or intermittent use
4. Operator: male or female age Average weekly earnings
other duties:
5. Experience with transcribing machine years Education
6. How is output measured: cyclometer other method
7. Is work done on a premium basis or number of points, or other standard based on production alone, or including quality, versatility, etc.
8. Number of characters and spaces which constitute a line
9. Is operator familiar with dictators' manner of speech
10. Does correspondence or other papers accompany cylinder to the operator for assistance in proper addressing and spelling
11. Method used by operator: sight touch
12. How much "rest" time is granted to operator: morning afternoon
13. Give any exceptional operations peculiar to the work studied that are not covered in the data asked for above.

TIME-STUDY SHEET

1. Number of lines to be typed 6, 12, 18, 24, 30. Count taps of typewriter keys and space bar and insert in heading of respective columns (letter work).
2. Number of carbon copies prepared.
3. Operations to be timed:

Column 1. (One set of studies only.) Select paper, insert carbon, place in machine, adjust platen to first line of typing, place needle in position on cylinder, adjust head phones.

Column 2. Type data.

Column 3. (One set of studies only.) Take paper from typewriter, remove carbon, place with finished work, check complete on cylinder indicator strip.

Observations; use bare time without any allowances	1	3	2

**PROCEDURE FOR MEASURING OUTPUT OF MACHINES FOR CUTTING STENCILS
OR PLATES USED ON ADDRESSING MACHINES**

Name

Date

Type of Business

1. Name and maker of machine
2. Model or style number Driven by hand Power Feed: Automatic hand
3. Is machine in constant or intermittent use
4. Operator: male or female age average weekly earnings
other duties
5. Experience on this particular machine Years. Education
6. Position of operator: Standing Sitting
7. Kind of stencil or plate used
8. Are only capital letters used
9. Does operator verify stencil as soon as it is made later or does another clerk check it State clearly, method used and average time taken for each plate or stencil.
10. How is output measured: cyclometer other method
11. How much "rest" time is granted to operator: morning afternoon
12. The making and inserting of name cards on addressograph plates must be considered as a separate series of studies. The same is true in the case of inserting the plates in frames. These should be attached to this study. It is an essential part of the operating of an addressograph but not on other types of addressing machines.
13. Give any exceptional operations peculiar to the work studied that are not covered in the data asked for above.

TIME-STUDY SHEET

1. Kind and size of document from which data to be cut is obtained
2. Is data prepared in (a) longhand (b) typewriting (c) clean (d) corrected. A study should be made of each variable in "1" under condition (ac), (ad), (bc) and (bd), and any other method. Use separate sheet for each variable and condition.
3. Provision is made for 1-2-3 and 4 line plates. If other sizes are desired, in addition, change headings accordingly. *Count the number of digits or strokes of the machine under each heading*, and insert in space for that purpose.
4. Prepare runs of 10-25-50-100 for each variable and condition. Check quantity used for this study.
5. Operations to be timed:
 - Column 1. Pick up and insert stencil or plate in machine.
 - Column 2. Cut.
 - Column 3. Take out stencil or plate and place in tray.See paragraph 12 for further operations on addressograph.

PROCEDURE FOR MEASURING OUTPUT OF DUPLICATING MACHINES, GELATIN ROLLS

Conclusions from Measurement Survey. A survey in which the foregoing procedures and time study sheets were used has provided a great deal of interesting and valuable data:

Age, experience, education, earnings and sex apparently had no definite bearing upon results. In several cases where the individual devoted her entire time to the job she was more proficient. This state, however, did not require years of experience to reach.

Approximately 90 per cent of the operators were females. About 95 per cent of these were less than 25 years of age. The earnings on the average were equivalent to \$1 a week for each year of the operator's age, up to 25, viz., a nineteen-year-old operator received \$18 to \$20; while a twenty-year-old operator received \$19 to \$21, etc.

Grade and high schools each supplied about an equal portion of the operators. A few business college graduates were included. A review of the output on this basis proved that there was no definite line between operators due to education.

As a rule, the operator about 20 years of age, with one to two years experience produced more than the others. This seems to indicate that the work studied has a fascination for young people who learn quickly. If they remain on the same type of work they lose their enthusiasm, and their efficiency drops.

It is extremely important to note that the time required to operate the device is far less than the get ready and clean up time. In these two steps there is a great opportunity to improve the total volume of output. Each step involves many motions, location of accessories, paper, and other equipment, which can be more efficiently handled and arranged.

The poor condition and arrangement of data may prevent a capable operator from producing maximum results. Usually such conditions can be bettered without inconvenience or expense.

Measurement Studies. The data in the following tables represent careful compilation of individual studies made by different organizations. They can be used as a yardstick for measuring results in the particular class of work which each represents.

Output of Transcribing Machine Operators. Sixteen members submitted data. The earnings of the group average about \$25 a week. There is apparently a definite relation between output and earnings. It is important to note that the "get ready" and "clean up" times are far in excess of typing time, therefore, consideration should be given to these elements.

Output of Duplicating Machine (Gelatin Process) Operators. Practically all of the studies were made from masters typed with hectograph ink.

The age of the operators varies from sixteen to thirty-two years. The youngest is as fast as the oldest. Length of experience has no effect on output as the quickest time is taken by an operator with one year while the longest time is taken by one having about four years' experience. However, those who devote their entire time to the work show better results than those who have other duties to perform.

Output of Addressing Machine Operators. Twelve members submitted data.

OUTPUT OF TRANSCRIBING MACHINE OPERATORS

The earnings vary from \$14 to \$30 a week. The output is apparently not related to the earnings. Speed is not a matter of years of experience but rather one of adaptability. Those with one year's experience are as speedy as those with five years.

Attention is called to the time required for "get ready" and "clean up." These two elements greatly exceed the time taken for actual running of the

machine. As the machine speed is a known quantity the real saving can be made in the foregoing two elements. A study of the file cabinets in relation to the machine may provide a source of real economy.

In a few cases the get ready and clean up times are high. This is due to the number of trays pulled from and refilled in the cabinet (see tables on pages 914 and 915).

Output of Typists (Includes Stenographers). Nineteen members submitted data.

With a few exceptions the time taken for actual typing is about the same for all operators. This uniformity is in direct contrast to the variation in age, experience, and earnings. A peculiar coincidence in this group is that the age of the operator expressed in dollars is about the earnings each receives.

Output of Operators Cutting Stencils or Embossing Plates. The age of the operators ranges from seventeen to thirty-seven years. The rate of earnings is from \$14 to \$28 a week. The latter is paid to an operator who is thirty-two years old, six years of experience, and only fair in output.

There are so many variables in these studies that it is difficult to obtain fair comparisons. The copy from which the data is taken is a large factor in the time to do work.

The tabulation may be helpful as a guide.

MEASURING, STANDARDIZING AND COMPENSATING FOR OFFICE OPERATIONS

BY MARION A. BILLS, *Assistant Secretary, Aetna Life Insurance Company*

For many years clerical operations were considered as a by-product of the important elements of business, a necessary evil, which like an incurable disease, it was best to bear with as little thought and discussion as possible. It has long been recognized that the difference between an efficient and an inefficient sales policy could make or ruin a business. Therefore, sales policy and sales personnel have received attention. On the other side, it has been recognized that a product must be manufactured at as small a cost as possible in order to meet competition, and factory operations have been studied. The clerical force, which in most businesses constitutes a relatively small portion of the organization, has, until within the last five or six years, received relatively little attention.

The clerical worker in fiction, and many times in life, has been pictured as an effeminate individual, stoop-shouldered, near-sighted, working long hours over books and figures, of the meaning of which he knew little. Dickens with his description of Cratchit in his "Christmas Carols," gave us the picture of a clerk which has persisted through a generation.

Increase in Clerical Work. In the last ten years the exceedingly rapid growth in the number of clerical workers and the growth of many big businesses such as banks, insurance companies, and mail-order houses, where the clerical group forms a very large proportion of the workers, has led to the necessity for scientific study and a more just evaluation of clerical work.

In 1890 there were 800,000 clerical workers, according to the United States Census. In 1920 there were 2,950,000; that is, the number of clerical work-

ers increased in those thirty years three and one-half times, while the general population increased from 62,000,000 to 105,000,000 or less than twice.

This is the direct result of larger business units. In part this large increase in clerical workers stated in the census is a fictitious figure, in part a true one. For example, in a one-man store the owner keeps his own books. For the portion of time which he devotes to this, he is a clerical worker, but no census would list him as 20 per cent clerical. The business grows to five times its original size, one person's entire time is devoted to keeping the books and he is listed as a clerical worker. In this way, as long as business units are small, the number of persons classified as clerical is no index of the total amount of clerical work done. The percentage increase shown when the partially clerical job becomes wholly clerical is really fictitious. On the other hand, no one who has analyzed the matter can doubt, that the actual clerical work necessary in performing any operation, increases as the size of the business units increase. To take an example of what I mean in this connection: In practically all life insurance companies, applications on which policies have been issued are filed numerically by policy number. There are companies that have as low as 10,000 policies in force and there are companies which have over a million policies in force. Now, it is obvious that the location of a needed application is easier in a file containing 10,000 applications than in one containing a million.

Or another example: One insurance company was founded by a doctor. There is a story, based without doubt on fact, that as he made his rounds he carried in his saddle-bags application and policy forms. When he came to a likely prospect, he sold him insurance, had an application made out, then as chief underwriter and medical examiner of the company passed on the application, issued the policy, and collected the premium. Here the clerical work was reduced to a minimum. No correspondence concerning the case was necessary, no memorandum on special conditions was needed, and further information required was immediately obtained from the original source. These are extreme cases, but they illustrate at least two ways that clerical work increases with increase in volume.

No Relation between Size and Efficiency. There is, of course, an idea that an increase in the amount of business automatically and without planning will cut down the clerical cost. This idea has grown up because clerks are very seldom kept 100 per cent busy and slight increases can be absorbed without extra cost. Also decreases in volume, since they are seldom followed by an immediate decrease in the working force, usually mean an increase in cost. The average person noting this, assumes the reverse to be true. But substantial increases, unless they are counteracted by standardization and planning, mean extra clerical labor. One reason is that the number of persons who handle, or are interested in the transaction, is increased. Each must be notified and must adjust himself to that transaction. Another reason is that increase of bulk increases the difficulty of locating any particular item. That there is no automatic relation between volume and cost of operation is at least intimated by a study of the Home Office salary cost per policy in force for eight insurance companies. The author had studied each of the companies in detail and the figures given are as close as could be obtained for relative costs. The companies are listed in order of size:

Rank in Size	Rank in Efficiency
1	5
2	4
3	1
4	8
5	6
6	7
7	3
8	2

As can be seen, there is no relation between size and efficiency. The fact that in nine out of ten growing businesses some one suddenly wakes up to the fact that clerical costs are too high, illustrates how these costs can mount with an unguarded growth.

Need for Standardization. Because of this increase in clerical work with the increase in size of business units, it becomes exceedingly necessary, if unit costs are not to mount beyond reason as business grows, to introduce easier methods, to standardize practices, and to obtain from the clerical force their best efforts. These are the three lines of attack. A prerequisite to any of these lines of attack, as in fact for any scientific study, is some means of measuring the item which is to be improved, whether it is cost, speed of operation, accuracy, or any other factor. It is a fundamental law of learning that one is only able to improve when one knows whether or not each effort is successful. For example, one could never learn to play golf if one did not know after each stroke the direction and distance that the ball had been sent. We cannot improve in the management of an office unless, with the introduction of each new method, we know whether the object for which that method was installed has been accomplished. Also, we cannot expect to get the best effort from any of the workers unless they likewise know when their efforts have been successful, and here, perhaps, we must add a psychological factor—unless they realize that the success of those efforts will be in some way recognized and appreciated.

Introduction of new methods and standardization so often go hand in hand that their consideration can best be taken up together. It is often easiest, when a new problem presents itself, to consider it as an isolated case and act on it accordingly, but this is safe only if the general laws of management have become so thoroughly a part of one's subconscious self that one uses them without thought. With most of us, this is not so and we need to subject every new problem consciously to all general laws. This not only often prevents our proceeding incorrectly, but indicates the proper mode of attack. We wish to continue the discussion of method and standardization by quoting four of these familiar, but perhaps not fully recognized general laws, and by illustrating their application. We shall purposely keep the illustrations very simple, since more elaborate ones, to be clear, would involve descriptions of life and casualty insurance.

Standardization of any operation usually means that that operation can be done in a much shorter time. This is because with standardization we get a large group of operations of a similar nature brought together and an operation often repeated can usually be so methodized that it can be done in a

much shorter time than a less frequently occurring operation. However, *if a large number of exceptions creep in, the entire gain may be lost.*

The lessening cost of any operation accompanying standardization, and the immediate increase of that cost when exceptions must be made to the standard, is perhaps simply and well illustrated by an experience of the renewal department of the Aetna Life Insurance Company. This department sends out premium notices and receipts, or in the ordinary terms of business, it bills the customer. These renewals and receipts are run off on an addressograph. They are then checked with the cards having the ledger accounts between the company and the policyholder, are placed in an outlook envelope, and run through a mailometer for sealing and stamping. The total clerical salary cost of sending out the renewals last year was less than three cents per renewal. We had a criticism come in from a policyholder that we were wasting company money. This policyholder had two renewals coming due the same month. The policy numbers were widely separated, the insurance having been issued in different years. The renewals were being mailed to him in two envelopes and he felt that we were wasting postage. In order to bring these notices together, that is, to break the standardized procedure, it would be necessary to keep a tickler account, showing that in that month and on that date the two renewals were to be sorted out and put together. The clerk doing the work would then have to get the two bundles, draw out the renewals, and put them together in an envelope. Clerical time is worth about one cent a minute. We figure that the least possible time that it would take a girl to look up a tickler record, pull out the renewals, and enclose them is not less than seven minutes; that is, in order to save two cents postage we must spend seven cents to handle the case specially.

Not only must the number of possible exceptions be considered in any standardization, but often they form the solution of a case where the cost of a process after standardization has for a time decreased but has then gradually begun to increase. An illustration of this we found in our Life Application File department about a year ago. The time taken to withdraw an application from the file had been decidedly reduced. It began to go up. This would naturally result in more clerks and in increased cost. An investigation was made and it was discovered that one division was sending most of their requisitions "rush" instead of through the regular routine. The time necessary to look up a rush case is 1.225 minutes as against a routine case, where a bundle can be taken together, of .522 minutes. A little explanation and cooperation again reduced the time, by reducing the number of rush cases. This saving of a little over half a minute a case is of consequence in the average withdrawal of 2,000 applications a day.

Often a salesman or an executive who does not understand clerical procedure will ask for information which is just sufficiently different from that being regularly given out to make it necessary to handle a large number of cases specially. Sometimes this is necessary, but often an explanation of exactly what it means in minutes or better still, dollars and cents will lead to an adjustment which leaves most cases standard.

Whenever you increase the number of people handling any transaction, you increase the clerical work. This increase may, of course, be overbalanced

by the increase of efficiency on account of specialization and standardization, but it is an item which should be considered. In fact, to every company having a rapid increase in business and coming to a point where methods must be radically changed, two courses lie open. *One is standardization and specialization of the operations* so that progress from person to person is systematic and so that each operation on account of specialization is done with the greatest ease and despatch. *The other is the breaking up of the force into small independent units* each handling different cases but handling those completely. Most life insurance companies have followed the first course. One very large company has, however, except for service or machine operations, virtually become seven small companies, each handling business from a limited territory. The efficiency and cost per unit of this company is about average so it forms no special argument one way or the other but it makes one realize that the principle of small unit operations may have broader application than we generally realize.

We have, for the reason previously explained, tried to keep our illustrations simple. The first of the two following illustrations demonstrates that the extra work, created by a distribution of operations, can at times best be eliminated by decreasing the number of people handling the case.

In the New Business department of the Aetna Life Insurance Company as in every new business department, the underwriters have had to correspond with the agent on a large number of cases. There were letters to be dictated on each of these. In this work the underwriter had to dictate the letter into the ediphone, the record had to be collected, taken downstairs, transcribed, the letter checked, sent back to the underwriter, reread by him, signed, and sent out. It was found that 50 per cent of the correspondence could be covered by a form letter on which the underwriter indicated by a check the item concerning which he wished additional information from the agent. Now on half of the correspondence, the file never leaves the hands of the underwriter. He enters the agent's name, marks the information desired, signs it, and is through with the case. Our time records show that the underwriter actually spends less time on the case now than previously. Besides, time is saved that was formerly spent in getting the work to the ediphone operators, in their transcribing it, and in getting it back to the underwriter.

The second illustration is a case where standardization seemed to show the greatest field for saving. The Aetna Life Insurance Company, as do most insurance companies, carries a card which is the ledger account between the policyholder and the company. Information from this card is used by a large number of people, and any payments from or to the policyholder or other information must be written on the card. For many years the people who need information from the card got that information direct, and any one needing to write information on that card, wrote it on himself. This worked very well so long as the company was small, but as the company grew, it became too difficult to locate cards which were out of file. For example, the posting of a premium to the card from the daily accounting report from the agency takes only .642 minutes if the card is in file, but when the card is gone from the file, it may take anywhere from ten minutes to several hours to locate it. In another company, where it was decided to leave the files of the

ledger cards open, the situation became so bad that at one time they had thirteen people who were doing nothing but hunting lost cards. With the chance of the exceptional cases becoming as numerous as this would indicate, it seemed time to make some change in the mode of handling. It was decided that it was best to allow only a few people access to the cards and have the others request information from the cards or notify these what was to be posted on the card. This, of course, was actually increasing clerical operations, since requisitions and notifications must be written, but it was decided that the saving in time with the elimination of cards "out of file" would more than make up for the extra clerical work. This has proved true, since increased work has been taken on with no increase in personnel.

It is sometimes difficult to locate what the real objection to a change in method is. For example, in the Claim department of one company, thirteen people are handling each claim, and it keeps two people busy locating claims needed. However, any plan for the centralizing of these claims so that they could be more easily located, has met with strenuous opposition. The explanation was finally determined upon, but it has as yet been impossible to make a change. The claim examiners feel that they are people apart, that their time is too valuable to be devoted in any sense to routine. They are very much afraid of doing any work which is beneath them. This same feeling extends down through the department. Therefore, we have a case of each person doing only one type of thing on the claim papers, and passing them on. In some instances this Ford type of production might prove most successful but claim papers are often very complicated and thirteen people are having to study a file and get into their minds an entire group of facts in order to do in many instances a minor operation. This is most wasteful of time.

It is most helpful to have a general rule that when the comprehension of the case takes any large portion of the time of the operation, as far as possible, one individual should do all that can be done in his department as one continuous operation.

Another fundamental law that leads to interesting and often productive speculation in considering many operations is that *whenever possible, it is cheaper to check in total than to check each individual item*. Here of course, you have a chance of compensating errors but that is a thing which occurs sufficiently rarely so that one does not need to adjust an entire system on account of it. An illustration of the working of this principle we find in the *Ætna Casualty and Surety Company*. For many years the branch offices, after checking the payment of any premium on their ledger cards, notified the home office of the payment of that premium and the home office checked the premium on their ledger cards. Now the home office notifies the agent of the total amount of premiums for which they must account. The agency reports the premiums collected and shows proof of cancellations, adjustments and additions. At the end of the period, the totals must balance. The elimination of the individual checking at the home office saves about \$40,000 a year in salaries.

The comptometer versus the adding machine is an example of this. If work is to be checked back item by item, the tape machine is necessary but if two totals may be checked, the comptometer is much the faster machine.

There is a story of the country cousin who was visiting a New York business man. As they were coming up in the subway from lower New York, the New Yorker rushed his cousin out at ninety-sixth Street, crossed the platform, and got into a car. As they settled down, he said with considerable satisfaction, "There, we saved a minute by that transfer." "Yes," the country cousin said, "but what are you going to do with the minute?" The same question should be asked about every saving in clerical labor concerning which one is thinking. *There is no use of making a saving in clerical time unless one can use that time to profit.*

The possible speed of operation of any person varies over a very large range, and there is, as a rule, an automatic adjustment of our speed to the amount of work which we find ahead of us to do. For this reason, a division which seems to be, and in fact really is busy all the time, often can increase its production under pressure 40, 50 and even 70 per cent. It is a question of habit of work, and when one has formed a habit of working slowly, it is very difficult to speed up. On the other hand, if one forms a habit of working rapidly, one does much more work with no more strain. This is true for routine clerical jobs and for the more technical or executive jobs. Nothing is more pernicious than the habit of slow work. Therefore, a decrease in the amount of work to be done, unless it is taken advantage of, may actually defeat its own purpose by causing an undesirable habit of work.

If a division does not have enough work to do, or if that work is exceedingly spotty, it is very essential that something be done so that the people work rapidly while they work, even though there are long periods when they do nothing at all. The only way that we have found it possible to keep up speed of operation during slack periods is by some type of measurement and payment for efficiency on a basis of the work turned out in a given time, and a definite allowance which does not penalize the individual for the time during office hours in which there was no work for him to do.

Of course, working rapidly while one works and having free time which is clearly and definitely so labeled, has another advantage to management. It shows clearly the basis on which any supervisor can work in estimating the amount of work which his department can handle, and preparing for it. In other words, surplus time then becomes a visible asset on which one can definitely plan. If the clerical forces are working slowly, the surplus time is a concealed and unknown asset concerning which the supervisor can only guess. Under these conditions the supervisor usually guesses incorrectly the actual surplus time available, and invariably underestimates the capability of his division.

It is usually much easier to take advantage of surplus time made available by any change in method, standardization or conscious increase of effort in a medium or large department than in a small one. Of course, taking advantage of surplus time is usually easiest when several people are doing the same work but though it takes a little more planning, it is usually possible with surplus time involving several jobs so to join the operation that a reduction in personnel and cost can be made. There are other arguments for the larger units such as full time supervision which we will discuss later, but flexibility of clerical force plays an important part.

Obtaining the Best Clerical Effort. The best methods fail if the workers are ineffective; therefore the second phase of office management, getting the best effort from the clerical workers, is as important if not more so than the first, standardization.

The first two steps in this, the proper selection and training of persons for the work, are studies in themselves and cannot be discussed here. The third step is the offering of proper incentives to the employees for their best efforts. This is a problem because the direct incentives for economic management have largely disappeared in the big businesses of today. The shoe-makers of a generation ago who made and sold their own shoes had their incentive to keep quality up and expense down constantly at hand, since if they did not give proper quality at a reasonable rate, people would not buy their shoes and unless they sold at a profit, they could not live. Today the person recording the sale of those shoes receives a fixed salary and the week to week salary does not directly depend on the profit made in the shoes. Of course, if the clerical worker looked far enough ahead, he would see that to have the business and his own job continue, the shoes must be sold and the accounts kept at a cost which leaves a profit but this is very vague and usually entirely out of the control of the person doing the individual job. Also, if a definite profit is made in the business, the individual doing the job is not at all sure of profiting directly by this increased profit of the company. Realizing this difficulty, many companies have adopted profit sharing plans. As a rule, however, these profit sharing plans have not allowed the individual worker, whose idea of business administration is of course meager, a means of definitely relating his own work to the profit which he receives. Therefore, his incentive for lessening expense is too vague to be wholly successful. If we are to get back in large businesses the real incentive that we have in the smaller units, we must connect directly the saving of expense and the remuneration of the individual. That is, the pay of the individual must vary as nearly directly as is practicable with the kind of work, the quantity of work and the quality of work done.

It is surprising how little any of these items were taken into consideration thirty years ago and even up to within the last ten years. We smile now when we talk about the regular annual increase, regardless of kind of job or efficiency but in practically every large clerical group during those years executives were giving small annual increases to every clerical employee who was not sufficiently inefficient to be asked to resign. One only needs to go over the pay roll of a number of large companies of long standing and discuss the various people with any officer understanding their jobs, to find innumerable cases where people are still doing the simplest routine work and have been doing it ever since they came with the company but whose salaries have grown by small increases so that they are paid, two, three and even four times what the job that they are doing is worth. A study made by three companies of the careers of all of the people who were on their payroll in 1908 indicates that about 50 per cent are still employed by the companies and that 30 per cent of the 50 per cent are receiving salaries which greatly exceed the maximum for the job which they are doing.

Classification of Jobs. The first step in advance perhaps came when people started to differentiate between types of clerical work and name them, and a really big step came when people began to realize that these general terms did not always designate the type of work done by the individual. For example, we have the much misused term of "bookkeeper." In different companies we find bookkeepers who are simply posting clerks, a job which they could learn in a few weeks, and bookkeepers who need to be expert accountants. It was then an easy step to the realization that the kind of work can be determined by a job analysis and job classification. Gradually it is being recognized that clerical work falls into the same classes regardless of the business involved; therefore, experience on classification is being rapidly collected.

Classification of jobs, of course, includes the resultant idea of the setting of salary limits for each class of work. The general principle is that we have for any class of work a minimum wage below which it is not fair to pay the clerk and a maximum wage above which we cannot afford to pay, no matter how well the work is done. That is, the kind of work sets the minimum and maximum salary to be received. The quantity and quality of the work done should determine the individual's position between this minimum and maximum. This is often the more difficult problem of the two to meet, although it does not, of course, involve large chances of injustice of payment. In order to meet this problem of determining the individual's position between the minimum and maximum, a large number of rating scales have been devised. Most of these rating scales are considerably better than nothing but no one of them has proved entirely satisfactory or probably ever will, since all are based for the most part on the personal opinion of the supervisor unsupported by actual records. Here we come back again to the thought which we have emphasized so many times, that if we can find some means of actual measurement of this quality and quantity of work done, we shall have a far more satisfactory method of salary adjustment than by any rating scale. Experience with actual measurement has shown us that even though we do not have a measurement which is 100 per cent perfect, we still obtain by means of these measurements, outstanding results in fairness of salary administration. If we add to this, pay on the basis of work done, we have a strong incentive for continuous and quantity production.

In our own classification, we have differentiated between two types of work—first, supervisory work, second, personal work. We make arrangements so that a person doing both supervisory and personal work shall be rated according to the higher class but we are convinced that the best management demands that units and divisions be made of sufficient size that a supervisor can devote the major part of his time to supervision. We believe that this is a correct principle for two reasons: First, *the person doing personal and supervisory work will in nine cases out of ten neglect supervision for personal work* and this is true no matter how much you may emphasize the importance of supervision. There are various reasons for it, most of them probably subconscious. For example, there is no one on whom he can lay the blame if the personal work is not done correctly and there are various other people he can blame if the supervisory work is not effective. Also, one always seems

to be busier when doing personal work, than when supervising, and most people like the feeling of being busy. Second, *approaches to the two kinds of work are quite different, and do not as a rule fit into each other.* Probably all of you can recall cases of people who have seriously overworked themselves trying to do the work of a whole section instead of seeing that the other people in the section did the work. The supervisor of the small group is very likely to be the person who has grown up in the work and has the viewpoint. When the job includes no personal work you eliminate the possibility of this. Third, the mind of the supervisor should be free so that he not only can see that the present work is going through satisfactorily but also can look for improvements in methods of operation, efficiency and cooperative services rendered to other divisions.

Importance of Measurement. Obtaining the best efforts from both the supervisor and personal worker depends on the same items. They are a knowledge of exactly what they are doing and how they are improving, a just appreciation of the improvements and an opportunity to make further improvement. One of the best things that can be done for any supervisor and which will give him a strong incentive for improvement if he is progressive, is to establish for him some fair unit of measure of the work of his division. It is not particularly difficult to find this unit for practically any division, as it does not have to be an exact unit but can be a unit with which other units vary. For example, with the renewal or billing department, it may be the number of renewals or bills sent out. This naturally does not take into consideration changes and corrections made but since they vary fairly consistently with the number of bills, it is permissible to select it as a measure. The supervisor should either be able to reckon this figure himself each month or should have it given to him with all the necessary data. Besides that, he should be made to feel that proper emphasis is placed on his record and proper appreciation shown. He should likewise know and agree to the job analysis and resultant classification of all the people under him, so that he can discuss their salaries with them intelligently and give them incentives for taking on more responsibility.

For the individual worker or personal worker, the measurement of their work and a money incentive to improve that work will often produce almost miraculous results, even after good supervision is apparently getting excellent results. Very often several changes are made at once and therefore it is difficult to isolate the effect of improved supervision, measurement of work and payment for production. We happen, however, to have had one division where these different modes of incentives were tried out, one after the other, and where we can, therefore, note their successive effects. In a small section of the Ætna Casualty and Surety Company, certain ledger cards are typed. Our first records show that these were being typed at the average rate of five an hour. The supervision was changed and with a little urge the operators went up to an average of nine an hour. Then individual records were begun which went to the officer in charge each month and pride was appealed to as well as the incentive of the knowledge that on the basis of the work, there would be yearly an adjustment of salary. The average number typed went up to twelve an hour. At this point an actual time study was made of the

operation and a bonus put on the work. Within a few months the production went to twenty-eight an hour with the same percentage of errors as previously. Half of the force were transferred, and those left are earning a bonus of between \$15 and \$20 a month which, on the salary paid for routine typists, is a very fair percentage.

While this illustration has been specially quoted because it shows the individual steps, the final result is not at all out of the ordinary. To obtain results, however, two items, as we have emphasized, are essential—good supervision and accurate measurement. While some supervisors of long standing resent any suggestion that the efficiency of their division could be improved by measurement of the work done, practically all of the younger and more progressive ones feel that such measurement gives them a chance to show what can be done and an assurance that when it is done, it will be appreciated. They also feel that it gives them a chance to justly estimate the amount of output which each of the employees whom they are supervising should be able to produce and therefore gives them a chance to more justly recompense those individuals.

A practical illustration carries out the principles which we have discussed here. For this I will take two divisions in the Aetna Life Insurance Company, the Renewal and Accounting. These two divisions have been chosen for general illustrations several times because their functions are more easily understood by an outsider than the functions of the technical departments of insurance. The functions are in general terms, the billing of our policyholders and the accounting for the premiums received. In 1924–1925 a complete analysis of these departments was made. Job descriptions were written up for all jobs involved and the relation of these jobs to the seventy agencies distributed throughout the United States were studied. At the end of the survey there were two young and very progressive supervisors in charge, men who knew the work thoroughly as it was being done but who were on the lookout for improvement. Nine-tenths of the success of the two divisions is due to their work. A rough unit of measure was worked out for the work of the division. This unit was the number of bills or renewals sent out. It was then considered by the supervisors with the idea of reducing this cost per renewal. An entirely new addressograph system was installed and a change made in the number of reports sent in from the agency and in the responsibility of handling these when they reached the home office. Besides that, the jobs were classified according to the classification which has been used throughout the company and several other large companies. In March, 1926, at the time that the work was definitely taken over, there were 114 people in these departments, with an average yearly salary of \$1,067. Today there are sixty-six people in this group with an average salary of \$1,368 plus an average bonus based on production per person of \$139, making a total of \$1,507. The number of items handled has meanwhile increased 90 per cent.

The decrease in cost has been made, first by a *change in method*; second, by *classification of jobs* so that increases in salary were granted on a more scientific basis and persons who were over the maximum of their jobs were not allowed further increases; third, by *setting up a budget* which the super-

visors kept constantly before them; and fourth, by a *measurement* for individual workers and the payment to them of a *bonus based on their production*.

In analyzing results of this kind, it is very difficult, of course, to say what proportion is due to any one of the various factors. Such results certainly would not have been accomplished without excellent supervision. The fact that there was a definite measure of successful operation gave these supervisors an added incentive for this work. A realization on the part of the workers that an attempt was being made to evaluate their jobs properly, gave them an incentive for knowing the work and a willingness to take over further responsibility. A definite study and payment for output of the individual worker, which really means an immediate recognition of his reduction of expense of the operation aided in this reduction in cost, a reduction which on a salary basis amounts to \$21,176 yearly. When we consider this, with the decrease in overhead due to the decrease in people, and take into consideration also the 90 per cent increase in production, we find the saving amounts to a very sizable figure. Expressing it another way, there has been a decrease in cost per renewal of more than $4\frac{1}{2}$ cents which, since there were slightly over a million renewals sent out last year, means a large saving.

Training Supervisors to Think in Terms of Cost. Measurement will often achieve another result which is sometimes difficult to get in any other way. In most companies that have had large forces for some time, the supervisors have grown up in a régime that gauged the importance of the job by the number of people supervised rather than by the kind and quantity of work produced. It is very difficult to teach supervisors trained in this school the idea that when they reduce their force for any reason whatsoever, they are not actually reducing their own importance. It is easy to see how such an idea developed. The craftsman of few generations ago could gauge his success by the number of fellow-craftsmen who gathered around him and the number of apprentices he had. The biographers of Benvenuto Cellini boast of the number of metal workers trained by him. Josiah Wedgewood spoke with gratification of the numbers who came to be instructed and the paternal factory owner of a generation ago pointed with pride to the numbers dependent on him. The importance of cost did not need to be emphasized with these men because under kingly patronage, they did not need to consider it, and as owners it was brought forcefully to them.

This prevalent idea of preceding generations together with the fact that most men like the feeling of power over their fellows made it very easy to build up the assurance of high correlation between the number supervised and the importance of the job. The very stability of the job of the office worker and the fact that there was no immediate relation between his income and the profit and loss of the business, has helped to cement this idea more firmly. To get these supervisors to think in terms of cost instead of people is a long, slow job. Sometimes the cost figures which they are asked to work out every month for themselves and which are regularly discussed or which are worked out by some other person and given to them with all details, will at last gain their interest. In exactly the same way a classification of jobs which is explained and insisted upon each time that the salaries of their employees are considered, will get them to thinking more in terms of the ability of their

personnel and the actual kind and amount of work accomplished, than in terms of length of service and the personal financial needs of the man. Often after a job classification and a rating has been in force for some time one finds the supervisor making a conscious analysis of the personnel of his department, which he would not have thought of doing previously.

The value of these older supervisors with years of experience behind them, when they begin to think in terms of progressive management cannot be overestimated. They have a first-hand experience gained through close contact with the job which can never be replaced by short-time studies. It is in the end really the supervisor who makes any system effective. Therefore, any time spent in inbuing him with new ideas and studying his constructive criticism of them is apt to be exceedingly productive of lasting results.

CHAPTER VI

OFFICE SERVICES

BY EDITH KING DONALD, *Editor, American Management Association*

Whether office services such as filing, mailing and messenger work, duplicating, stenography, and computation should be centralized or decentralized will be determined by the size and nature of the operations to be performed. When a survey determines that the sum total of a certain class of decentralized work will not justify the existence of a separate service department it will then be more economical to let that operation remain in its existing locations. Considerable savings are possible through centralization, but convenience and the confidential nature of some work argue for decentralization.

Factors Determining Specialization. Some of the factors which determine the need for specialization or separate service departments are:¹

1. What is the volume of work of a certain operation such as typing? It is not desirable to create a department if a total of only ten or fifteen hours of the special work is being done each day by five or six secretaries.

2. What degree of specialization or amount of training is required to do the work?

3. What type of help is available in the departments requiring special service? For example, if it is found that several high-salaried men are doing calculating operations or are tabulating certain data or are making maps, etc., and there is enough of the work to keep several clerks busy, it may be more economical to organize a clerical unit to do the work.

4. Are the working conditions conducive to doing the special operation? It may not be advisable to furnish the desired heat or quiet condition in the operating department, which factors are needed for efficient production of the specialists.

5. Is the supervision in line departments adequate?

Special supervision, even for a few clerks, may be more economical. The line executive and his assistants may be fully qualified for carrying on the major function but very poorly qualified to supervise, or even give general direction to the carrying on of a special operation.

When certain work such as filing, typing, etc., is for good cause centralized, these operations may with a degree of satisfaction be brought under operating standards by detailed job analysis, establishment of written routine, and scheduling of the work of the individual. Departmental supervision as well as periodical staff checkup will be necessary to keep the standards

¹ Adapted from I. O. ROYSE, "Organization for Office Services," American Management Association, 1931.

effective. Past production records cannot be considered adequate for comparison and as a basis for operating standards.

If centralized work is done by as many as twenty to thirty clerks in each department, an attractive saving should certainly result over the decentralized plan. The advantage of centralization comes from close supervision, possible standardization, measurement, scheduling, incentives, development of a highly skilled group by careful selection, assignment, and training, etc. Cases are on record wherein centralizing the secretarial activities into a transcription department using business phonographs has reduced the original force by one-half, has reduced the amount of equipment, increased production considerably, and released a very substantial amount of valuable floor space.

The effect on overhead is greatly influenced by the type of supervisor available. A good supervisor should be able to control two or even three different service groups, performing different functions. This, together with the other savings resulting from centralization tends to decrease rather than increase overhead expense.

Safeguards on Centralized Service. To guard against excessive and unnecessary requests for office service, the following will help:

1. There should be a definite understanding concerning the services offered.
2. Service department heads should be clearly instructed concerning the type of work to accept.
3. There should be a director of all office services.
4. A cost system should be established and the departments serviced should be charged for the work done. If there is a proper budget system this is usually very effective in eliminating useless requests.
5. Periodically check work should be done in the major departments such as sales, accounting, production, etc. to determine the load carried by the employees in the departments.
6. The work in all departments should be analyzed and scheduled and there should be a definite understanding that only certain specified work be passed from each department to the service groups.
7. In cases of questionable jobs being assigned to service groups, the work should clear through the service director for analysis, decision and, if accepted, assignment.

The Supervisor of Office Services. One person should have supervision over service units. It will be an exceptional organization that can have service units operate long, efficiently and harmoniously under two or more line executives. Theoretically the executive in charge of service units should report to the general manager, president, or a senior executive who is in general charge of the line executives who have departments requesting work from the service groups.

The supervisor of office services, sometimes called "office manager," should have line control over only those employees who are working in the service units in his charge and not over employees who are perhaps doing similar work in the major operating departments. At the same time the office service supervisor may exercise a research function in simplifying and standardizing clerical work. This is sometimes found in medium sized

offices which do not have sufficient volume of such work to warrant the establishment of a central planning or research department. In such cases the office service supervisor acts in a staff capacity in relation to the supervisors of the other departments. He may suggest methods and standards of work for employees not under his direct control, but is not responsible for the discipline or output of such employees.

In many small offices the clerical work incident to the major functions of finance, accounting, sales, production and personnel is centralized under an office manager. Insofar as the volume of work will permit such an arrangement, it may be effective. If any or all of these activities grow to the point where separate departments are necessary, difficulties may arise through the implications in the title office manager. A clear definition of function and assignment of authority in such a way as to avoid cross currents of authority and division of responsibility is necessary in order to avoid the ructions and delays that may be caused by anomalous titles.

Danger of Overcentralizing. It is easily possible to overcentralize services. If proper budgetary, cost, or supervisory control does not exist there may be danger of line departments passing work to centralized service departments to reduce their own expenses or to avoid the trouble of caring for the work in the line department. In the well organized and controlled office there will be in existence the proper planning, scheduling, and control to determine very closely the conditions under which there should be centralized service departments and there will also be a continual check to avoid abuses as well as to encourage proper use of the service units that it is found advisable to have.

Advantages and Disadvantages of Centralized Service. Some of the advantages of central office service departments are:

1. Peak loads may be more easily handled.
2. Supervision may be more adequate.
3. Expert advice from highly trained supervisors is available concerning methods.
4. Higher production will usually be attained at a lower cost per unit of work.
5. Standards may be established and more easily enforced.
6. Greater facility leads to convenience in many cases such as in finding correspondence.
7. Better rating of clerks and often better remuneration is possible.
8. Better and more uniform work should on the average be turned out.
9. Greater flexibility exists in rotating workers during vacation and sickness.
10. There is usually a reduction in investment on account of less machinery being used and decreased floor space, etc.
11. Output is often increased by possible economic use of machinery which would not otherwise be economical.
12. Service departments are often very good training departments to provide highly efficient help for other departments.

Disadvantages of centralization which must be overcome in building successful service departments are:

1. Lack of knowledge of the purpose and use of the clerical work done may remove the interest or incentive for speed and accuracy from the service worker.

2. Work may be so involved and irregular that errors and explanations prohibit centralization.

3. An organization may be so constituted that each major activity is separate from any other and quick access to records so desirable that centralization is not practicable.

4. Interdepartmental service such as messenger service, must not lag in the face of the greater burden due to centralization.

5. Extra forms or reports necessary to insure proper control of services rendered should be kept as simple as possible.

It will be readily seen that careful selection and standardization of equipment will make for flexibility of operation, whether or not the work is all done in one locality. This is especially true of typewriters and filing equipment, and only less so of other types of machines and furniture.

Filing. The character of the business, or nature of departmental work in an organization will determine the system of filing which will best safeguard and quickly produce the material to be saved. Most general correspondence can be kept alphabetically, but because of their nature some papers are best filed numerically, geographically, by subject, by date, by a combination of number and letter, by commodity, port, or steamer, etc.

The use of color in forms, records, and in carbon copies of letters helps to make part of the sorting automatic. Colored labels on the guides in the file drawers to designate various divisions will also save time and mental effort.

An alphabetical file is economical because of its simplicity. It is operated without an index by separating correspondence into folders labeled with initial letters. Growth will bring problems in filing alphabetically. The main thing is to anticipate them in so far as possible by studying the expansion of the activities causing this increase in correspondence and by adopting arbitrary subdivisions of the alphabet and sticking to them.

Sometimes the size and variety of correspondence necessitates filing by subject with a numerical index. In this case the material may be divided into related groups, each group being given a number and subsidiary groups designated by a related decimal number, or number and letter classification. Two aids to classification are the Dewey Decimal Classification¹ and the Cutter Table.² The former was designed for general library use and those who are concerned with classification of business subjects may profit by making their own adaptation based on the decimal principle. The Cutter Table is a chart providing for expansion through the use of the letters of the alphabet plus numbers.

A basic classification of subjects occurring in a manufacturing business is:

¹ DEWEY, MELVIL, "Decimal Classification," Forest Press, Lake Placid Club, New York.

² CUTTER, C. A.: "C. A. Cutter's Three-figure Alphabetic-order Table," Northampton, Mass.

- A: Accounts and finance.
- E: Employees.
- G: Executive (general).
- L: Legal matters.
- M: Product (manufactures).
- P: Plant.
- R: Reports and statistics.
- S: Sales.
- T: Traffic matters and purchases.

Each of these main groups may be subdivided indefinitely through the use of additional numerals and letters. An alphabetical card catalog composed of cross references to these groups will help to locate material which is called for by people who think of the same material from varying angles.

The primary detail of classification under "Accounts & finance," "Employees," "Executive," "Product," and "Plant" is given below. This classification is in use in the manufacturing department of a large company. It has been developed on the principle of reference to an object rather than a function. The personnel who do the filing are able to grasp names of things, when functions would probably be beyond them. It will be noted that room for expansion between subjects has been provided.

- A: Accounts and finance.
 - A 5: Appropriations.
 - A10: Audits and inspections.
 - A15: Banks and currency.
 - A15B: Bank balances.
 - A15C: Cash.
 - A15N: Negotiable instruments.
 - A20: Bookkeeping.
 - A25: Classifications, accounting.
 - A30: Costs.
 - A35: Credit and collections.
 - A40: Depreciation.
 - A45: Expense and budget.
 - A55: Investment.
 - A60: Invoices and bills.
 - A65: Journal entries.
 - A75: Loadings.
 - A80: Transfers (accounting).
 - A85: Working balances and expenditures.
- E: Employees (personnel).
 - E 5: Accidents.
 - E10: Employment.
 - E13: Occupational classification.
 - E15: Performance.
 - E20: Service to.
 - E25: Thrift.
 - E30: Training and educational.
 - E35: Trips.
 - E40: Pay roll matters.
 - E45: Working force.
 - E50: Works' club.

- G. Executive (general administrative matters and subjects not otherwise classified).
 - G 5: Addresses and talks.
 - G10: Associations, societies, clubs, and institutions (other than employee clubs).
 - G12: Clerical inspections (general).
 - G15: Committees.
 - G20: Conferences, conventions, and meetings.
 - G25: Contributions and donations.
 - G30: Insurance (all, other than employees').
 - G35: Office service (include service only; correspondence on equipment should be filed under equipment affected).
 - G40: Organization.
 - G45: Relations with other companies.
 - G50: Publications.
 - G55: Publicity and advertising.
 - G58: Records and forms (include only those which cannot be otherwise classified).
 - G60: Routines (include only those which cannot be otherwise classified).
 - G65: Rules and regulations (company only).
 - G70: Suggestion systems.
- M: Product (manufactures).
 - M 5: Engineering and drafting (general).
 - M10: Manufacturing methods (general).
 - M15: Inspection (general).
 - M20: Production (general).
 - M25: Raw material and supplies (includes all supplies) (list A to Z).
 - M50: Manufactured merchandise (A to Z).
- P: Plant.
 - P 5: General subjects.
 - P10: Buildings (A to Z or numerically).
 - P15: Building areas (include equipment special to these areas) (list A to Z).
 - P20: Building construction.
 - P25: Floor space.
 - P30: Equipment.
 - P40: Grounds (include improvements such as fences, pavements, etc.).
 - P50: Passes and badges.
 - P60: Service (general) (does not include any systems shown under P30R).

Standardization through a Manual. As in every other phase of management a filing system to be effectively used must be adapted to the particular organization which it is to serve. After a system has been planned with reference to the activities of the business a manual describing it and giving rules for its maintenance will be found of inestimable value. A work routine describing filing done in one department and taken from the manual of procedure of the filing section of a large bank is given here as a sample of how standard practice may be developed and maintained.

DESCRIPTION OF FUNCTIONS

- I. Collection and preparation of mail for files.
 - A. Mail is gathered once or twice daily from the desks of the credit and business extension men.

B. This mail is reviewed by the head of the filing section to see if it is ready for filing. This is indicated by a round office-and-department stamp, and the initials of the person sending such material to the files. It is also checked with colored pencil at the name of the person or firm under which the paper is to be filed.

1. Credit mail is then passed directly on to the respective clerks for sorting and filing.
2. Business extension mail is also scanned for the following, before it is sorted and filed:
 - a. Changes of address.
 - b. Changes of firm name, consolidations, and mergers, etc.
 - c. Changes of department records (to another account, etc.).
 - d. Special interest accounts.
 - e. Note of official acquaintances.
 - f. New officers, and resignations of old officers.

All of this information is transmitted to the departments which would be interested.

g. "Fin" written across the upper-right corner of the letter or report, which, in business extension mail, is necessary (in addition to the stamp) to indicate readiness for filing.

h. Pencilled initials and a follow-up date, indicating that a follow-up card must be written for the paper and filed in the date file.

II. Sorting and filing mail.

A. Mail for each division is "thrown" (or sorted) into alphabetical order in a sorting tub.

B. Sorted mail is taken from the tub, arranged in strict alphabetic order, and further divided for each correspondent according to class and date. It is then ready for filing.

C. Filing entails fastening the new material in the proper date order in the correct division of the folder.

III. Types of material filed; material filed in credit and business extension folders comprises the following:

A. Credit material:

1. Financial statements of the firm.
2. Comparative statement (of financial condition) form.
3. General correspondence of credit value (largely with the subject).
4. Agency credit reports.
5. Newspaper clippings (of both credit and business extension value).
6. Open and closed account slips.
7. A "General Information" sheet.
8. Typed record (usually a "pink sheet") of lines established, and loaning officers' decisions.
9. Overdraft sheets.
10. Typed "information" sheets, upon which are entered summaries of interviews with and investigations of the subject, by credit investigators.
11. Offering tickets or slips.
12. Carbons of answers to incoming credit inquiries, or typed extracts of these.
13. "Verbal inquiry" sheet, noting inquirers and dates of inquiry.

B. Business extension material:

1. Notes of changes of address, and mailing list change slips.
2. General correspondence of business extension value.
3. Reports, interviews, etc., written up by field men and other business extension representatives.
4. Official acquaintance sheet, noting any acquaintance of the bank personnel with the subject.

IV. Sequence of folders in file.

- A. For banking offices, handling only a small amount of out-of-town and foreign mail, geographic divisions are unnecessary, and an alphabetic plan of folder sequence is best.
- B. For banking offices handling large amounts of out-of-town or foreign business, territorial divisions are important, and a geographic plan of folder sequence is best. In that case the material is thrown into geographic order at its first sorting.

V. Preparation of folders; individual folders are made up for every borrowing account, in the larger offices, for every account. There the procedure is:

- A. Reports of new accounts from the new accounts desk are listed upon the new account sheets (see VIII).
- B. The sheet is checked against the index.
- C. If there is no card in the index file, a folder and an index card (see VII) are prepared for the account.
- D. If there is a card marked "closed" for any of these names, it indicates that this account is a reopened, not a new, account. In this instance the card is drawn and changed and the folder is also drawn and its contents transferred to a new red-rope (account) folder.

(Individual folders are also made up for non-accounts, when there is material of any volume for one name. Miscellaneous folders are maintained to care for a few sheets of material for one name which is not an account of the office. Such small units are filed in alphabetical order within the folder.)

VI. Records of folders loaned.

- A. A requisition is made out by the borrower, in the larger offices, for every folder taken from file.
- B. "Out" folders or cards, written from the requisitions where requisitions are used, or as the sole record in a smaller office, are filed in place of all folders loaned.
- C. The requisitions are kept behind date guides in the same order as are the folders they represent.
- D. Each day the requisitions which have been outstanding for a week or more are checked against the files to ascertain whether the folder has been returned. If the file is missing, inquiry is made of the borrower as to whether it is still needed. Wherever the folder cannot be relinquished, notation is made on the requisition, which is then returned to the outstanding file. In offices where requisitions are not used, the out cards in the files are reviewed for note of overdue material, and, where it is found that any letters or folders have been out too long, inquiries are made.
- E. If the material is transferred from one borrower to another, a notice is sent to the filing section by the original borrower.
- F. When returned to the section, each folder is checked through before replacement in file. When it replaces its outfolder in the

file drawer, the out folder is gathered up with others, to cancel the requisition slips.

- G. It is advantageous, wherever practicable, to loan folders upon a single work-day basis, so that they will be returned to the filing section at the end of each day even though some of them must be reallocated to the same people on the following morning.

VII. Index to credit files.

A check list against the files is kept on cards (three by five inches), blue cards being used for customers and white cards for non-customers. This index shows:

- A. All names in file (accounts, non-accounts and material in miscellaneous folders).
- B. Changes of name, affiliations, etc.
- C. The location of material in the files.
- D. Material transferred to other offices.
- E. Material sent to storage.

The "new account sheet" is authority for changes and additions to the index, in the offices using this record.

VIII. Preparation of new account sheets.

Items for new account sheets, typed in this unit, are received daily and consist of:

- A. List of new accounts, from new accounts desk.
- B. Lists of closed accounts from head bookkeeper.
- C. Changes from:
 - 1. Field men's reports, letters, etc.
 - 2. Newspaper and magazine clippings, letters, etc., in which case the information is verified before it is entered.

IX. Average balance and loan cards.

- A. At the end of each month the depositors' bookkeeping department enters average balances upon average balance and loan cards.
- B. At the beginning of each month members of the credit and loan and discount departments make notations of loans upon these cards.
- C. The cards are then refiled in alphabetical order in a card file in the credit and business extension filing unit.
- D. These cards are withdrawn in the same manner as credit folders, and by the same officers or employees who are permitted to withdraw folders from the file.

X. Follow-up work for business extension division

A follow-up system is maintained for the benefit of the business extension division, but not for the credit department.

- A. Each morning, follow-up cards due that day are removed from the follow-up file, and then arranged in the same order as the files they represent.
- B. The folder corresponding to each card is taken from file. If not found in file, it is secured from the borrower to whom it is charged.
- C. These folders are grouped according to the individual requiring them, and placed on his desk.
- D. Out folders are then written up for, and filed in place of, folders given out. The corresponding follow-up cards are filed in the requisition slip file, under date.

XI. Records of transferred and closed accounts.

- A. Records pertaining to accounts transferred to other offices, and to closed accounts, are changed in accordance with the notations appearing on new account sheet, and are transcribed upon:

1. Index cards.
 2. Average balance and loan cards.
 3. Folder covers.
 - B. Folders stamped "closed" are returned to their respective places in file.
 - C. Folders representing transferred accounts are forwarded to the office to which the accounts have been transferred.
- XII. Storing of old records.**
- A. Once a year closed accounts and material in miscellaneous folders are submitted to the main users, the credit men, to be reviewed for transfer.
 - B. Transfer of material to storage is recorded upon the index cards.
 - C. Whenever shipment of records to the central warehouse is contemplated, (and, if possible, before the shipment is packed) the coordinator of files, general coordinating office, is notified.
- XIII. Records of work performed.**
- A. Daily record is maintained of the aggregate number of letters filed. The count is made as the mail is sorted and checked each day.
 - B. Requisitions for folders borrowed the previous day are counted and recorded each morning.
 - C. These records are summed up weekly and monthly in the form of reports, noting work done for each department.
 - D. A "control" record is maintained daily, reporting requests filed, those unfilled for known reasons, and those unfilled for unknown reasons.

Eliminating dead material from the filing cabinets by storing in transfer cases is necessary in order to save space and keep the files efficient and active. Transferring may be done periodically or continuously, as time beyond the current work will allow. The cost of storage space will necessitate a definite policy covering the destruction of dead records. Some material should be kept indefinitely while other records will have outlived their usefulness in a year or less.

The tickler or calendar file is operated by a series of guides labeled with the months of the year and days of the month. This file will automatically bring up matters which should receive attention at a particular time. In order to observe the principle that the general file should at all times be complete, a memorandum of the matter to be attended to may be inserted in the tickler.

For those firms who must file large numbers of documents by names which may sound alike but vary in spelling the Russell-Soundex system has been devised. This scheme groups all names phonetically, thus obviating a lengthy search for a name with unusual spelling.

A detailed and comprehensive treatment of filing is found in "Filing Department Operation and Control" by E. E. Scholfield. A simple and elementary text is "Filing Methods," by E. Wallace.¹

Combining Mail and Filing Departments. In some companies it seems practical to handle the mail and filing in the same department. The following

¹ Ronald Press Company, New York.

outline of operations in such a department will suggest how the work may be scheduled. It will be noticed that in this particular company the indexing of articles in technical magazines is also done in this department. This would ordinarily be handled by the company library.

FILE AND INCOMING MAIL DEPARTMENT OF A CHEMICAL COMPANY

1. Opening, routing, and delivery of incoming mail. 8:00, 9:30, 11:00 a.m.; 12:00, 2:00, 4:30 p.m.
2. Delivery of tickler correspondence. 9:00 a.m.
3. Coding of customers' correspondence and indexing of subject correspondence including making of cross references. 9:00 a.m. to 5:00 p.m.
4. Filing of coded and indexed correspondence. 9:00 a.m. to 5:00 p.m.
5. Answering requests on file department.
 - a. In person.
 - b. By telephone.
 - c. At a stated period, i.e., between 12 and 2. Letters which required answer sent to file department by sales correspondents.
6. Collections of correspondence. 11:00 a.m., 2:00; 4:30 p.m.
7. Typing of folders and labels.
8. Transferring at end of year.

Folders for large accounts made up ahead of time.
9. Indexing of articles in technical magazines. Index by subject and title on three by five inch cards which were filed in alphabetic order.
10. Semiannual reports on volume of work handled.

Mail. The effective handling of mail requires manual skill and considerable economy of time and effort is possible in the proper organization of this work. In the case of circularizing, or a large volume of ordinary mail, careful scheduling, attention to working conditions and equipment including arrangement of material, and training of workers in the best way to do the work will yield gratifying results. It is work which can readily be simplified, measured, standardized and is frequently paid for on an incentive basis. At least one person in an organization should be thoroughly conversant with mailing rates and rules.

Substantial economies are possible through the careful planning of circular mailing matter, particularly in the size and weight of the paper and envelopes involved. While this material originates in an operating department of the business, cooperation from the person supervising mailings is desirable in planning such matter.

Messenger Service. To a certain extent mechanical equipment, such as the pneumatic tube, belt conveyor, elevator, carriers on wires, replaces messenger service in large offices. Where this is not practical, the job of messenger is often regarded as a training ground for promotion to clerical work. The Harris Trust and Savings Bank has proved the value of this plan and uses uniformed girl pages for interdepartmental service.¹ A definite training and promotion plan has been developed for them, upon the completion of which they are always in demand for permanent jobs, usually in the departments in which they have been doing part-time work. **Messenger ser-**

¹ For a complete description of this plan see *System*, p. 23; 3, July, 1929.

vice can also be measured and standardized and is sometimes paid for by an incentive method.

Duplicating. Material may be reproduced in quantities through the use of carbon paper and the typewriter, and automatic typewriter, the mimeograph, multigraph, dupligraph, ditto machine, hektograph, blueprint, photostat, lithoprint, and printing from type. The character of the work and the number of copies to be made must be considered in determining the method to be used. The volume of such work should determine whether a particular sort of equipment should be installed. In large cities it is frequently less expensive to use the equipment of some firm organized for the purpose than to install special machinery which may have only intermittent use.

Stenographic. Standards and economy of production in stenographic work are brought about through attention to equipment, working conditions, policies of the firm, and selection and training of the personnel. Once the standard practice in this work has been developed it is essential to outline it in a work routine or manual, different sections of which may be designed for the use of dictators and transcribers.

Business phonographs have come into increasing use for this work, especially in large offices. The dictator's time is also saved by form letters and form paragraphs developed for use in routine correspondence. Typing from telephoned dictation is also being done effectively, especially in technical and sales departments. This work lends itself readily to measurement and is often paid for by an incentive method.

The functions of the Central Stenographic Bureau of the Metropolitan Life Insurance Company have been described as:

1. To furnish copyists and stenographic help to officers, division and department heads, section heads, and others,
 - a. Whose work is such as not to require the services of a permanently assigned employee.
 - b. Whose stenographers are absent from the office on account of vacation, sickness, or for other reasons.
 - c. Whose regularly assigned employees are not able to take care of a large but temporary increase in volume of work.
2. To select and train junior stenographers for permanent assignments either in the Central Stenographic Bureau or from the bureau to parts of the organization as vacancies occur, which assignments are usually in the nature of promotions.

Where the volume of the work warrants it, the above functions of a central bureau may be very effectively developed.

Computation. Calculations in any considerable volume are usually performed mechanically and machines for this purpose are described in Chap. III. The work is highly specialized, when performed most economically and necessitates training the operators. If there is sufficient volume of the work to establish a service unit it will also be desirable to train experts on particular machines. Remuneration for this work is often on an incentive basis.

Telephone, Telegraph, Radio. Training in the use of the telephone is important because of the impression given to the person on the other end of the wire who may form his opinion of a concern without ever having seen its personnel or offices. A telephone operator, having a good voice and properly instructed, can be a distinct asset to an office in that she can protect the executives from unnecessary interruptions by tactfully dealing with calls which need not have their attention. The use of the telephone for personal calls by clerks is discouraged in most companies, as it is apt to disturb those within earshot, and may monopolize wires which are necessary to the conduct of the business.

The telegraph, cable, and radio services are usually centralized. Information should be readily available as to the relative costs of these communications and their effectiveness as compared with the telephone and air mail. Special services not generally known are offered by companies supplying these means of communication and the literature describing them is available. If these services are used in any volume, it will be necessary to keep a record of all long distance telephone calls and other special communications in order that their cost may be allocated to the proper departments.

Reception of Callers. The importance of receiving callers adequately can hardly be overstressed. The initial and often lasting impression of a firm is gained upon entrance to its offices. In small offices it is often practical to have the telephone operator also act as a reception clerk. Larger offices frequently have for this purpose an elderly man or woman who is responsible and dignified. Long-service employees are suitable for this work, as they are apt to be generally familiar with the personnel and practices of the concern. Other duties which may be combined with the job of reception clerk are adjustment of complaints, coordination of all information service, handling of telephone and telegraph traffic, supervision of office boys and messengers, displaying samples and outstanding products of the organization, assisting at mailing desk, handling small incidental sales, and demonstrating products.

The degree to which the callers are handled successfully will depend largely upon the selection of the person to do this work. A job analysis and specifications for choosing the person to do the work will help to accomplish what the firm expects in receiving visitors. Almost invariably the character and policies of the administrators of the business are reflected in the reception clerk. The nature of the business and of its visitors will usually determine the sort of furnishings appropriate for the reception room, but the amount spent on a table, comfortable chairs, and a few magazines or other means of diversion for those waiting will be money well invested.

CHAPTER VII

FORMS: THEIR DESIGN AND USE

BY B. EUGENIA LIES, *Director of Planning, R. H. Macy & Co., Inc.*

One of the subjects which is receiving increasing attention is the question of forms and form design. Management is realizing more and more that forms, which were once considered necessary evils and universally condemned as so much red tape, can be made effective tools to simplify, speed up, and control work and thereby reduce costs. Forms, however, to be effective tools, must be properly designed from the point of view of accomplishing the purposes set, with a minimum of effort and the most economical materials. This paper will, therefore, deal primarily with the technique of form design and the analysis necessary on which to base the design.

Elements of the Problem. The material will be presented from the point of view of the analyst faced with a problem in form design. The following main divisions of the paper are therefore the elements of the problem which should be covered in the analysis:

1. What are the purposes of the form?
2. What information is needed before the form can be designed?
3. What principles of good form design should be kept in mind in designing the form?
4. What factors should be considered in determining the specifications of the form?

In conclusion there will be a brief discussion of the methods of controlling forms and of insuring the proper use and maintenance of forms.

Purpose of Forms

It is necessary to consider the two following questions before starting to design a form:

1. Are the purposes of the form justifiable?
2. Is a form necessary to carry out those purposes?

In general, all forms should be designed to fulfill either one or both of the general purposes, which are summarized by Wallace Clark in his book on "Shop and Office Forms,"¹ as follows:

1. "Forms provide the means of carrying out decisions and policies.
2. "Forms provide a basis for executive action, and for determining policies."

¹ McGraw-Hill Book Company, Inc., 1925.

If the purposes of the form can be justified, it then becomes necessary to justify a new form as the best means of carrying out these purposes. It is frequently possible to eliminate the need for the new form by using "as is" or modifying some form already in existence.

A thorough study of the entire procedure involving the form together with an analysis of the needs of the executives and departments to use the form must be made to determine adequately the purposes of the form and to justify the use of a new form. In making such an analysis we have found it helpful to use a process chart. For the discussion of this paper, we will assume that the entire procedure has been studied and the proper method determined.

Information Needed to Design a Form and Determine Specifications

It is of great importance to collect certain information about the form as a preliminary step in its design. The difficulty frequently is that the information on a form is inadequate to fulfill its purpose properly. Or as happens too often, in the anxiety to give complete information, the form is burdened with too much information. It is unnecessary for us to point out that putting too much information on a form is objectionable, not merely because of the additional paper that is required, but also because of the additional work required to fill in this information.

To simplify the collecting of this data, we have classified it into three groups, *i.e.*, data regarding:

1. Recording information on the form.
2. Using information which has been recorded on the form.
3. Handling the form.

To make sure that all the necessary information is collected we suggest the use of a tabulating sheet which will include all of the following headings. (Fig. 1.)

Recording the Information. Under the heading of Recording Information, list

1. *All of the purposes that the form is to fulfill. Beside each purpose, indicate the information which must be recorded in order to fulfill each purpose or function. If this is done, there is less danger of omitting important information or of including unnecessary information on the form.*

2. *By whom is the information to be entered on the form, i.e., the departments, the jobs, and the number of employees on each job?*

This information is very important as we shall see later when we come to discuss the principles underlying form design. The number of people on the job may be the deciding factor in the arrangement to be used on the form? It also aids in answering questions as to type of instructions to be put on the form, the quality of paper and types of binding to be specified, etc. This information is also essential as a check list to be used for consulting all those who in any way come in contact with the form.

3. *What is the source of the information to be entered on the form? Is it from other printed forms, from instructions received from some other employee or a customer, or is the information entered from the employee's own knowledge or resulting from judgment or calculations made from entries on the form?*

FUNCTION	RECORDING INFORMATION				USE OF INFORMATION				HOW SORTED	HOW FILED
	BY WHOM	BY WHOM	SOURCE	WHEN ENTERED	HOW ENTERED	BY WHOM	HOW	WHEN

FIG. 1.—Tabulation sheet listing information needed before determining the design and specifications of paid sent salescheck used by R. H. Macy and Co., Inc.

This information is very necessary in determining the arrangement of material on the form.

4. *When is the information entered and how frequently?* Consideration of this information is essential in order to determine the design as well as the specifications of the form.

5. *How is the information to be recorded?* Is pen, pencil, typewriter, or other type of machine used? Neither the type of paper to be used can be decided nor the best arrangement of the form determined unless the method of recording information is known.

Using Information Previously Recorded. So far, we have been considering the form from the point of view of the simplest method of filling it out. Consideration should next be given to by whom, how, and when the information entered on the form is to be used.

1. *By whom is each piece of information to be used,* the departments, the jobs, number of employees on the job?

2. *How is the information to be used?* Is it transcribed to another form or is it merely read by some one for information, or is it used for reference or as a basis for judgment. If data is to be transcribed from this form, the arrangement of the form to which it is to be transcribed and the method of making the transcription should be considered. If used for frequent reference the important information should stand out and be easily visible.

3. *When and how frequently and for how long a period is the information to be used?*

Handling the Form. Under the heading of Handling the Form, make a record of:

1. *The workplace layout* including all equipment and materials where information is recorded and used. It is impossible to design the form properly without knowing the entire set up of the surroundings under which the form is used.

2. *The method of sorting, the information by which the form is sorted,* such as name, or date, or number, or code symbol, etc., and *equipment for sorting.*

3. *The method of filing, the information by which the form is filed and the filing equipment used.* In this latter case, the information is important not only from the point of view of arrangement, but essential from the point of view of size specifications.

Principles of Good Form Design

Having collected all the information necessary in regard to the form, and tabulated it for quick and easy reference, we are ready to design the form. The general principle underlying all form design is that the recording and using of information on the form and the handling of the form will be performed with the greatest economy and with the fewest errors.

When it is impossible to design a form to satisfy all of these considerations, the question to determine is which consideration is most important and should therefore be given preference. The information previously gathered on types and number of people coming in contact with the form will help in making a decision.

The second decision to be made in designing the form is the number of parts or copies of the form needed. Consideration must be given here to:

(a) Original sales check. This form is divided into three main sections. The top section, labeled 'SENT SALES CHECK', contains fields for 'MONEY RECEIVED' and 'AMOUNT OF SALE'. Below this is a 'PERFORATION' line. The middle section, labeled 'Write D-A Number Here', contains fields for 'SALESBOOK SALES CHECK', 'DEPT NO', 'SALESCLERK NO', 'MONTH', and 'DAY'. The bottom section, labeled 'ORIGINAL', contains fields for 'APT.', 'NEAR', and 'SALESBOOK SALES CHECK'. A vertical line on the right side indicates 'Part in Package'.

(b) Triplicate sales check. This form is divided into three main sections. The top section, labeled 'Customer's Receipt', contains fields for 'MONEY RECEIVED' and 'AMOUNT OF SALE'. Below this is a 'PERFORATION' line. The middle section, labeled 'Write D-A Number Here', contains fields for 'SALESBOOK SALES CHECK', 'DEPT NO', 'SALESCLERK NO', 'MONTH', and 'DAY'. The bottom section, labeled 'TRIPPLICATE', contains fields for 'APT.', 'NEAR', and 'SALESBOOK SALES CHECK'. A vertical line on the right side indicates 'Part for the Bureau of Adjustments'.

(c) Duplicate sales check. This form is divided into three main sections. The top section, labeled 'SALESCLERK', contains fields for 'MONEY RECEIVED' and 'AMOUNT OF SALE'. Below this is a 'PERFORATION' line. The middle section, labeled 'Write D-A Number Here', contains fields for 'SALESBOOK SALES CHECK', 'DEPT NO', 'SALESCLERK NO', 'MONTH', and 'DAY'. The bottom section, labeled 'DUPLICATE', contains fields for 'APT.', 'NEAR', and 'SALESBOOK SALES CHECK'. A vertical line on the right side indicates 'Part for the Controller's Office'.

(d) Reverse of duplicate sales check. This form is divided into three main sections. The top section, labeled 'CASHIER'S STAMP', contains fields for 'MONEY RECEIVED' and 'AMOUNT OF SALE'. Below this is a 'PERFORATION' line. The middle section, labeled 'Write D-A Number Here', contains fields for 'SALESBOOK SALES CHECK', 'DEPT NO', 'SALESCLERK NO', 'MONTH', and 'DAY'. The bottom section, labeled 'INSTRUCTION TO CASHIER', contains fields for 'APT.', 'NEAR', and 'SALESBOOK SALES CHECK'. A vertical line on the right side indicates 'Part for the Controller's Office'.

FIG. 2.—(a) Original sales check. (b) Triplicate sales check. (c) Duplicate sales check. (d) Reverse of duplicate sales check.

1. The advantages or disadvantages of many copies as against the routing of a single copy.

2. The possibility of legible copies.
3. The appearance of the record.
4. The possibilities of loss.
5. The wear and tear, etc.

If a form consists of several parts or several copies, it is necessary to allocate the information to be put on each part or each copy of the form and then to identify each part and each copy either by name, by number or by color of paper or printing ink (see Fig. 2).

Accuracy, speed and usefulness depend on whether the form is arranged suitably or not. The following rules will be helpful as a guide in the proper design. Arrangement, more than any other single factor will measure the success or failure of the form.

1. Filing or sorting symbols should be conspicuous. The upper right hand corner should usually be reserved for the filing information or filing symbols or reference numbers or identification marks or code symbols, or whatever is the information by which the form is to be sorted or filed. In those cases where it is impossible to use this space, it is necessary to consider the entire handling of the form in deciding on the best part of the form to be used.

2. Provide boxes in which information can be entered. The use of boxes in which information is placed is preferable to more lines, for it results in a neater form and is not confusing even when there are a great many items to be filled in. The printed box limits the employee to recording within the box, which is not the case where lines are used.

The printed headings in the box should be set in small type, usually in a six-point Copperplate Gothic and should be placed close to the upper left hand corner.

3. Arrange the information on the form in the same sequence as it is arranged on the forms to which or from which the information is transcribed.

4. Group information by departments. Errors will be reduced and saving of time result if all information recorded or used by one department is grouped so that it will be unnecessary to search for it.

5. In designing spacing for hand written forms, consideration should be given to the type of employee using the form. Clerical workers as a general rule can write on lines spaced four to the inch, or even, at times, five to the inch. For quick entries or for employees not used to clerical work, spacing of three lines to an inch should be used.

6. If forms are to be typewritten, lines are usually unnecessary. When lines are necessary, the horizontal ones should be spaced three to an inch, which is double typewriter spacing. The reason that double spacing is preferable to single spacing is that box titles cannot be printed in the space available when the typewriter is single spaced. Vertical lines should be spaced in multiples of one-tenth inch for typewriters having pica type and one-twelfth inch for those having elite (small) type.

7. Where the form is to be made out on a duplicating or other kinds of machines, special consideration should be given to the requirements of the individual machine. Space in this paper will not permit a detailed discussion of this point. Warning is, however, given from experience that this should

not be the only consideration in designing the form. Frequently the handling and use of form is sacrificed to supposed mechanical requirements.

8. Definite economies will usually result if wherever possible the information is confined to one side of the form. If it is found necessary to print both sides of the form, an effort should be made to have complete information on each side of the form to eliminate necessity of turning. If this is possible, it would be well to consider whether it would be more economical to have two separate forms printed on one side only. However, before deciding, consideration should be given to the following:

a. How the form is used.

b. The cost of printing on two sides of heavy paper as against two separate printings on light weight paper, for if two sides are used, the form will get about twice as much use, and in the case of bond paper where transparency is a factor, it may be necessary to substitute ledger for bond.

c. Savings in filing equipment. If both sides of the form are used, less filing equipment will be necessary.

9. It is usually desirable to print instructions for the use of the form on the form itself. These instructions should be clear and concise and should help in reminding the individual when in doubt as to how the form is to be used. Where the form routing is complicated, and the people using the form do not come in frequent contact with it, it is desirable to make the instructions more detailed. The type of employee using the form should be considered. In most cases, however, the general rule mentioned first should hold, for if too many instructions are put on a form, the employee may not read them at all. Complete instructions can be recorded in instruction cards and manuals.

Instructions should, as a general rule, be placed on that part of the form where they can be read or consulted easily. Various schemes have been used by different companies in the printing of instructions. Instructions have been made part of the title, printed at the bottom of the form, or in the binding margin. Some organizations have even found it profitable to number the columns and then print separate detailed instructions, referring to the columns by number.

10. If the form is to be filed, consideration should be given to the type of file to be used, and the following points decided:

a. If a visible file, what information should be visible and whether the form should be visible at the top or at the bottom.

b. If vertical files, whether the filing symbol should be conspicuous and whether the paper is of proper weight.

c. If bound in a loose leaf binder, has sufficient binding margin been allowed? The variations in binding margins may be from one-half inch for ring binders up to two and one-half inches for some types of post binders. For the guidance of our organization, we have prepared the following chart to determine the proper type of binder to specify (Table I).

Specifications of Forms

After the form has been properly arranged, it is necessary to determine the detailed physical specifications of the form. The following is a discussion of these specifications:

TABLE I.—DETERMINING TYPE AND GRADE OF STANDARD LOOSE LEAF BINDER TO ORDER

Type	FACTORS DETERMINING TYPE TO BE USED*				FACTORS DETERMINING GRADE NUMBER TO BE USED				SPECIFICATIONS FOR GRADES			
	Capacity	Simplicity of inserting and removing sheets	Writing surface	Wear on records	Life	Temporary 1 yr. or less	Semi-perm. 1-5 yrs.	Perm. 5-10 yrs.	Grade 1	Grade 2	Grade 3	Grade 2A
Ring	Small (About 300 sheets) of 20 lb. paper on 1½" ring	Best	Very good Flat	Records subject to hard usage	Mild Normal Rough	1 1 2	1 2 3	2 3	Low grade artificial leather. Light weight chip board. No end opening lever	8 oz. Duck. Medium binder's board. End opening levers	Fabricoid No. 3000. Medium or heavy wt. (depending on size). Binder's bd. End opening levers	Grade 2A
Prong	Limited (About 400 maximum)	Best	Very good Flat	Records subject to hard usage but not as much as above	Mild Normal Rough	1 1 2	2 2 3	3		8 oz. Duck. Metal heavily nickel plated. Heavy wt. binder's bds.	Fabricoid No. 3000 Metal heavily nickel plated. Double binder's bds.	
Post	Unlimited	Good if insertion or removal is consecutive. Otherwise poor	Fair Varies with contents (The more sheets in the book, the worse the surface)	Slight wear	Mild Normal Rough	1 1 2A	1 2 3	2A 3	8 oz. Duck. Canvas hinge. Top lock. Medium wt. binder's bd.	8 oz. Duck. 2 oz. Cow-hide sides and corners. Corduroy Metal hinge & metal caps. Top lock. Medium or heavy weight binder's bd (depending on use)	2 oz. Cow-hide sides and corners. Corduroy Metal hinge & metal caps. Top lock. Medium or heavy weight binder's bd (depending on use)	Same as 2, except Endlock
Thong (Kalamasoo)	Practically unlimited (limited to size of back)	Good, irrespective where sheets are added or removed	Good	Slight wear	Mild Normal Rough	1 1 2	2 2 2	3 3 3		Standard Kalamasoo binder. 8 oz. canvas	Standard Kalamasoo binder. Leather	

* If portability is a factor a ring book with flexible covers is usually the best type—although no strict rule can be laid down.

1. Paper.

a. *To determine kind of paper.* In form work the papers most commonly used are manila, bond, ledger, index, bristol, tissue and special papers like mimeograph and ditto. To determine the kind of paper to be used, it is necessary to determine how the information on the form is recorded and used.

- (1) If recording with a pencil, manila paper is frequently sufficient.
- (2) If the form is used on only one side, bond papers can usually be used.
- (3) If two sides are used or if good erasing qualities are desired, ledger is usually necessary since ledger paper is of comparatively heavy weight.
- (4) If the form is to be filed in an upright position, Index Bristol is usually necessary. In some cases, however, where good erasing qualities are desired or where filing capacity is a factor, a thirty-two- or thirty-six-pound ledger can be used instead. This type of paper is most often used in visible filing equipments.

b. *To determine the grade of paper.* The studies made by the American Writing Paper Co. several years ago, are still the most reliable authority on this subject. For the purposes of this paper, we will merely mention some of the highlights.

In general there are two factors considered in determining the grade.

- (1) The life of the form, which is roughly classified into
 - (a) Temporary.
 - (b) Semipermanent.
 - (c) Permanent.
- (2) The character of the handling, which can again be roughly classified into
 - (a) Mild.
 - (b) Normal.
 - (c) Rough.
 - (d) Abusive.

There are other factors that determine grade of paper, such as impression or appearance. These, however, do not play an important part in Form work and will therefore not be discussed in detail.

Classifications as mentioned above are very rough. Expressions such as "mild" and "normal" are not measurable quantities. For that reason, the determination of standards for grade and weight of paper should be left to the purchasing agent and the systems manager in each organization. The importance of mentioning these factors in this paper is that too often paper is not considered at all and where printing is purchased on a competitive basis, the honest printer or the quality printer who is anxious to supply the best paper will lose out on the job.

A few general statements may be of aid. The life of the paper, as a general rule, depends on the materials of which it is made. Rags and wood pulp are the most common materials used in paper making. Papers made of sulphite are usually considered temporary, although time and time again sulphite sheets have been known to exist five and ten years. No one disputes the fact that the average paper made of rag, no matter how small the content

of rag, is better than the average sulphite sheet. Further than that we cannot go. A 35 per cent rag paper is not necessarily better than a 30 per cent rag paper. Some other measure of quality of paper is necessary, in order to determine permanence. To determine grade and weight of paper from the point of view of character of handling, the tensile, folding and bursting strength should be considered. However, manufacturers have discovered means of doping papers, so that the tensile strength and bursting strength are no longer reliable measures of paper strength and in a recent bulletin the United States Government (report of the chief of tests, 1926) recommends the folding test as the only sure test of paper quality.

As previously stated, we cannot with great precision determine on standards of quality necessary to withstand rough handling. For the present we have to leave the determination of the paper necessary to withstand a certain amount of handling in the hands of the people who are experienced in papers, guided by such information as the folding test will show. There is this further fact to be remembered, namely that a standard folding test takes place under standard atmospheric conditions. How the same paper will react under the conditions in which it is to be used is likely to be different than under standard conditions.

c. *To determine the weight of paper*, the following factors must be considered. These factors are self explanatory and to avoid taking any more time we will merely mention them.

- (1) Treatment paper is to receive. (This is a factor, since the heavier the paper, the stronger it will be.)
- (2) Number of carbon copies necessary.
- (3) Is stiffness necessary in order to aid filing?
- (4) Is the sheet so large that it requires weight to make it lie flat?
- (5) Is form to be mailed? If so, a lighter weight may be desirable to save postage.
- (6) Are both sides of the paper to be used?

d. *To determine the color of paper*. It is preferable to avoid color as much as possible in papers as an index for the copy. The use of numbers or even differently colored ink is often more desirable. Color may be used however

(1) To distinguish a copy where many similar copies are handled by any one department and where the printing is so small that a printed identification mark will not be easily visible.

(2) When two similar forms appear in one place and quick distinction between the two is necessary as an aid in the sorting operations or for some other reason.

(3) To represent something distinctive or pertaining to a particular function or department.

(4) If the form is to receive a great deal of handling, buff is most desirable for it reduces the glare and does not soil as easily as white.

2. Size of Form. Size is a very important factor in effecting savings since:

a. Papers are manufactured by mills in standard sizes and if the form does not cut evenly from the stock size, a loss due to waste of paper will result. The most common standard sizes are 17 by 22 inches, 17 by 28 inches, and 19

by 24 inches, and the doubles, sizes 22 by 34 inches, etc., for bonds and ledgers. The standard sizes for indexes are $25\frac{1}{2}$ by $30\frac{1}{2}$ inches, $20\frac{1}{2}$ by $24\frac{3}{4}$ inches and $22\frac{1}{2}$ by $28\frac{1}{2}$ inches. In designing the form, the size of the form should be multiples of the dimensions of the standard sizes. Thus the standard correspondence sheet $8\frac{1}{2}$ - by 11-inch cuts from a 17- by 22-inch and a 3- by 5-inch index card cuts from the $25\frac{1}{2}$ - by $30\frac{1}{2}$ -inch size. We therefore repeat, where forms are designed with no regard to the standard size of papers, a great loss in printing is bound to occur.

b. Savings in printing can be effected if the printer can combine two or three different jobs by putting them on the press at the same time, if the total size of the forms is equal to one of the stock sizes of the sheet. This is very common where large presses are used. There is no waste due to the "left over" if the order is in standard sizes and in quantities using an entire ream. The expense and waste of time of having special size files and binders made is also avoided by the use of standard size papers.

The following points should be kept in mind when deciding the size of the form.

a. In specifying the size of the form to the printer, allow an extra one-sixteenth inch all around for trimming.

b. Do not use a square form if it is necessary to sort the form. It is easier for the person handling the forms to determine the top or side of a form if dimensions indicate it.

c. Other things being equal, forms should be as small as possible and still accomplish their function effectively. The enthusiastic standardizer, however, should be warned that the savings effected through simply reducing the size of the form have been unduly emphasized. Frequently the cutting down may result in lessening the value of the form because not enough space is allowed for entries. As a matter of fact, paper cost, while an important element, is nevertheless only a small part of the printing cost and a small reduction in size in the average case does not make a very great difference in the final cost, certainly not a difference sufficient to justify the reduction of space, headings, etc., to a point where they are insufficient for the most effective use.

3. Ink. There is an unlimited range of color in the inks which may be used in printing. Except under special conditions the least expensive color to use, both from the point of view of cost of ink as well as cost of handling, is black. While we know of no conclusive evidence to prove that the color of ink has a tremendous effect on eye fatigue, it seems reasonable to believe, and most authorities agree that buff and green ink produce the minimum of eye strain. We have standardized on buff and green ink for rulings (replacing many colors). Under these same conditions we use buff paper whenever the handling problem justifies special consideration.

If colored inks seem desirable as a means of differentiating various forms or parts of forms, it is well to remember that if more than one color is used, the form must usually be run through the printing press twice, thereby adding to the cost. When a great many copies are ordered and if the printer has a two-color press in his plant, then two color printing may be used at practically no additional expense. It is advisable, whenever possible, to use only one color, for when the form is reprinted and another printer bids on the

job, the price may be figured as a two-color printing and thus the expense may be increased. A word about the use of red for printing numbers. We have found that the red number is less distinct and likely to produce more errors than a black number.

4. Type. In general there are three groups of type, heading type, reading type and novelty type.

a. Heading Type. For headings such as captions on forms, identification marks, etc., we use Copperplate Gothic. It is clear, neat, and easily read. When heading needs to be attractive a Goudy italic is generally effective.

b. Reading Type. Where a great deal of reading matter is grouped together as in instructions, some form of Roman type, such as Century is most desirable. The seraphs at the end of the letters, the upper and lower case, and the possibility of using italics, bold, extended, or condensed type, makes this a very flexible means of conveying the thought to the reader. It is not very ornamental and its appearance does not detract from the contents.

c. Novelty Type. Novelty type should be used only where it is desirable to attract the attention of the reader, or where appearance is the most important factor. We have not felt the need of any extensive research in this phase of form design.

5. Ruling. All rulings add to the expense of the form and should therefore be used only when absolutely necessary. When the use or appearance of the form requires the use of lines, printed rules should be used unless the design of the form justifies pen ruling.

A brief description of the method used in pen rulings will help to show how costs can be kept to a minimum. For every line appearing on the form a steel pen is placed on a board. The spaces between the pens are the exact spaces between the lines on the form. A piece of flannel soaked in the color of ink that is to appear on the form is placed above the particular pen. The ink from this flannel provides the pen with the ink it needs for ruling. A belt conveyor runs underneath these pens. The sheets of paper are placed on this belt conveyor which carries the paper under the pen and the pen rules the lines.

Cost of pen ruling is based upon the length of time it takes to do the job, which depends chiefly on the following two factors:

- a. The time required to set the pens.*
- b. The time required to rule.*

Every pen-ruled form must pass through the machine once when the vertical lines are ruled, and again when and if horizontal lines are ruled. Horizontal lines are usually ruled by pens set in gangs. The unit of measure or the distance between pens is one point or $\frac{1}{12}$ inch. Horizontal lines should be spaced 12, 13, 14, etc., points to the inch. Twelve points is $\frac{1}{6}$ inch, and it is felt that seldom if ever should the distance between horizontal lines be less than this. Eighteen-point, that is $\frac{1}{4}$ -inch, spacing is quite common.

Vertical lines are nearly always ruled by individual pens so that the distance between vertical lines may be anything at all. Fluid ruled forms should be so designed, however, that as many vertical lines as possible start and stop

at the same point on the sheet. It may happen that the starting of several vertical lines at different points on the sheet will necessitate that the form be passed through the ruling machine twice or more for the ruling of the vertical lines, thus increasing the cost.

The expense of securing proofs of rulings is tremendous and therefore usually prohibitive. It is, therefore, necessary to have specifications for rulings perfect since no corrections are possible. It is even more necessary to have accurate specifications for a ruled form than for a form for which a plate is to be made, for the loss in case a plate is wrong, is merely the cost of the plate, while if the rulings are not specified correctly, the cost is the labor of setting up the machine, the time the machine has been operated, and the entire value of the paper for the job.

For color of rulings, see above, under color of ink.

The test of quality in ruling is:

- a. Accurate spacing.
- b. No overrunning of lines beyond the intersection.
- c. No short-stopping of lines before the intersection.
- d. Clear, sharp, evenly and uniformly colored lines.

6. Carbon. If carbon is to be used with the form designed, and if the form is to be padded or bound in book, specify the carbon desired so that the printer will supply the carbon in the exact size, fitted into the pad or book.

There are three types of carbon: pencil, pen, and typewriter.

a. Pencil carbon.

Pencil carbon can be easily recognized by the soft, dull, thick, and uneven surface of the carbon side. Such a carbon is necessary for pencil in order that the dull point of the pencil may leave an impression on the copies. There is also a light weight pencil carbon obtainable which resembles typewriter carbon. This light weight is to be used only when many pencil copies are necessary. Sharper copies usually result from this carbon, but it requires more pressure than the other carbon by using a hard pencil and a stiff support.

b. Pen carbon.

A pen carbon is similar to a typewriter carbon but has a very high sensitive film covering it and is therefore suitable for use with steel pens.

c. Typewriter carbon.

These carbons are the least expensive but are satisfactory for use only with typewriter. They are thin, fairly durable, and produce many copies.

The factors in quality of carbon are paper, color and coating. The paper determines the durability of the carbon. The coating determines the quality of the carbon. A poor carbon will give blurred impressions, smear a great deal and result in soiling the hands of the operator handling it.

7. Binding. Forms will be delivered by the printer in any manner specified:

a. The cheapest way is loose. The printer packs the forms in bundles of 50, 100, or 500 or in any other quantity specified. Cards, tags, loose-leaf sheets are usually delivered loose.

b. Pads. The advantages of pads are: ease of handling supplies; an aid in eliminating waste (reduces spoilage by holding the forms together and makes possible the use of carbon).

c. Bound books. This is the most expensive way of delivering forms. It should be used only where absolute registration of carbon copies is necessary or where one copy is necessary for permanent keeping and circumstances make it desirable that this copy be kept safe from the moment it is issued.

There are many types of bound books for forms. The most common styles of bindings used by the average concern are:

- (1) Wire stitched Kraft top chip board box.
- (2) Light weight press board or imitation press board covered book.
- (3) Medium weight press board or imitation press board covered book.
- (4) Printed jute board covered book.
- (5) Heavy weight printed jute board covered book.
- (6) Marble board covered book.
- (7) V-tongue book.

In order to determine the proper type of binding to specify, we have prepared a chart (Table II), shown below, which shows the facts that must be considered to determine the binding. This chart has been designed for the needs of our own organization, and is shown here merely as a type of analysis necessary in order to standardize bindings and not as a general guide to be followed by all organizations.

Where the work place is limited in size and the manifold book is large, manifold book manufacturers produce a book known as flapback, which is an ordinary book with a special hinged cover so that the front cover may be turned completely back and underneath the book cover.

8. Numbering. Forms can be numbered with little additional expense, if a space of 2 in. x $1\frac{1}{2}$ in. is allowed for the numbering machine and if the number to be desired is to be printed in the same color ink as that of the form. The size of numbers depends upon the standard numbering machines supplied by manufacturers.

9. Punching. If forms are to be placed in a binder, they must be punched for the binder to be used. The common methods of punching are:

- a.* Round holes generally used for ring binders.
- b.* Slot holes for use with post binders.
- c.* Special punching such as required by the Kalamasoo Binder, the Brooks Visible or other special binders.

If a form is to be bound, it should be designed to fit one of the several standard size binders. There is such a range of standard binders that this should not be difficult. The holes, of course, should be spaced so as to fit the binder in which they are to be placed. Sheets for ring binders are usually punched with either $\frac{7}{32}$ -inch or $\frac{5}{16}$ -inch holes, depending to a large extent on personal preference except that the larger holes are nearly always used if the binder has rings $1\frac{1}{2}$ inches or more in diameter. Holes in forms to be filed in a post binder should be $\frac{1}{32}$ inch larger than the post, *e.g.*, for a binder with $\frac{3}{8}$ -inch posts, the hole should be $1\frac{1}{32}$ inch in diameter; for

a binder with $\frac{5}{16}$ inch posts, the hole should be $1\frac{1}{32}$ inch in diameter; for a binder with $\frac{3}{16}$ -inch posts, holes should be $\frac{7}{32}$ inch in diameter. The post sizes above mentioned are those in general use.

Table II.—TYPE OF BINDING TO SPECIFY

Handling book receives			Reference to copy remaining in book	Size limitations	Style number specified	Remarks
Normal	Rough	Abusive				
<i>x</i>	None	None	1	Form is numbered and a stronger protection than padding is necessary
<i>x</i>	Infrequent	$8\frac{1}{2}$ by 11	2	Cover not strong enough for upright filing
..	<i>x</i>	..	Frequent	None	3	Suitable where flexible covers or use on the outside is desired; cover will resist weather
..	<i>x</i>	..	Frequent	$8\frac{1}{2}$ by 11	4	Good filing record if not over $8\frac{1}{2}$ by 11
..	..	<i>x</i>	Frequent	None	5	Good filing record
..	..	<i>x</i>	Constant	None	6	Good filing and good appearance
..	..	<i>x</i>	None	None	7	If used in great quantities, the savings in binding costs will warrant the purchase of covers

Loose leaf binder manufacturers have prepared tables of standard gauges which should be consulted before the form is settled.

10. Perforations. Perforations are of three major types.

- a. **Press perforations**, perforated by the printing press while printing. It can be recognized by the coloring of the perforation. This perforation when made on a job press is not very reliable for it is just as likely to come through perforated too deeply as perforated too lightly. It is inexpensive and is to be used on inexpensive forms, where the neatness of the job is not an important factor.
- b. **Plain perforation**, made by the printer on a perforating machine, in a neat, uniform perforation, especially desirable on tags.

- c Pin perforation, made on a perforating machine, is the strongest of all forms of perforation. It is as expensive as the plain perforation mentioned above.

If there is danger of the parts becoming detached before use, specifications to the printer can be made to perforate only a small portion of the form and leave one-fourth an inch or one-half an inch at each edge unperforated. Salesbook perforations—The perforations made on the salesbook or rotary printing presses are similar to the plain perforations mentioned above. If there are no numbers on the form, the perforations can be arranged in any manner. However, economical use of rotary presses requires that perforations be parallel to the numbers appearing on the form.

Methods of Controlling Forms

It can readily be seen from this discussion on the design of forms that the analysis to be made before the form can be designed as well as the proper designing of the form is a technical job and requires training and knowledge. In order to get the proper results, this work cannot be left in the hands of inexperienced people or assigned to individuals who do not feel the responsibility involved. As has often been said, a form is a management tool, and like all tools, if improperly designed, does damage by causing work to be ineffective as well as by wasting the form itself.

It is therefore advisable to designate an individual, or, if the organization is large enough, a division of trained analysts who will specialize in the study of system, its proper analysis and the design of forms. To avoid the printing of forms on the spur of the moment, and to insure that forms requested are necessary and properly designed, the systems division should approve all forms before they are purchased. This division should also approve all changes and discontinuance of forms as well as new forms. It will be found that a division of this type is not only best qualified to do the most effective job in form design, but can also bring about greater cooperation between departments and greater uniformity in the systems in all branches of the organization. Each form should be registered with a number or symbol to aid in classifying and stock keeping.

The job of the systems division should not end with introducing the forms. Changes desired on established forms already in use should be referred back to the systems division to be analyzed by the same procedure as was used before installing it, for a changed system is in reality a new system to replace an old one, and requires as careful a study as a new system does.

Even slight changes should be referred to the systems division to avoid the danger of not securing the approvals of all the executives who originally approved the form. Too often, forms are changed at the request of one executive who in his haste may overlook the fact that many other departments in the organization are using the same form. This reference to the systems division will also avoid hasty changes that consider savings but not the cost. By cost we mean, not only equipment but the cost of repairing errors, etc.

It should be made clear to all the members of an organization that a system introduced cannot and must not be changed unless all executives who originally approved the system, approved the change. A great danger that is always existent lies in unauthorized changes made by individuals using the system, without securing the proper approvals. These changes are usually the result of temporary emergency measures, and are continued after the emergency ceases. We have, therefore, found it advisable to issue together with every system, a standing order which relates to the system as a whole, and an instruction card for each job coming in contact with the system. These standing orders and instruction cards must be followed as written, until a change has been properly authorized. Unless these steps are taken, all the effort put into designing the best form for a job goes to waste.

CHAPTER VIII

OFFICE PLANNING AND CONTROL

OFFICE LAYOUT

BY ORRIN G. SHERMAN, *Assistant Secretary, McGraw-Hill Publishing Company, Inc.*

The Purpose of Proper Office Layout. An adequately planned office will reduce the cost of doing business. The economies will arise out of the following considerations which are the aim of proper office planning:

1. To provide sufficient and not excessive space for each individual and for the working unit based upon careful examination and analysis of all of its requirements.
2. To provide working conditions conducive to the highest state of working efficiency and comfort, in keeping with the tasks to be performed, and representative of the character and standing of the business organization.
3. To facilitate supervision, control, and the flow of work through the office by means of proper layout, intercommunication facilities, and mechanical contrivances.
4. To provide for expansion, if and when necessary, with the minimum amount of disturbance and expense.

The size of the office affects these considerations only in that the amount of saving possible will increase with the size of the unit under consideration. Therefore, any technique described can be simplified or extended to meet the requirements of varying conditions in office size. The opportunity for economy in very small office units is often surprising.

Who Should Do the Job? The office manager is obviously the proper person in the organization to carry the responsibility for analyzing this problem and working out its solution. In smaller organizations there is usually someone whose duties correspond to those of office manager. It may also be desirable to call upon professional management engineers for help and cooperation. In any case, the problem warrants the very best of scientific analysis and a handling of it that will secure and hold executive support and organization cooperation and achieve the maximum beneficial results.

When Should It Be Undertaken? Correcting faulty office layouts is usually not thought of or is deferred until the organization decides to move to new quarters. Examination may show that the savings arising out of improved layout will pay for the cost of the change in a short time and remain as a credit thereafter. The examination may show that a move to other quarters is desirable or that a move to larger quarters may be deferred

At So Many Dollars per Square Foot per Year. A contract for office space rental is usually entered into for a period of years. In the congested business areas of large cities these rental charges per square foot per year are high, and each unnecessary foot taken will therefore write itself into the cost of business operation for a corresponding period of years. These improper space standards are also likely to affect estimates of space needed for expansion and in this secondary manner they again inflate rental costs. It must also be remembered that inadequate space standards result in decreased working efficiency which, while not always directly measurable, is present just the same. A careful analysis is necessary to determine the correct amount of space to be assigned for the various office tasks and their equipment.

Other Losses Not Always Evident or Measurable. The productivity of the individual worker (and this is more true of the office than of the industrial worker) is dependent in part upon the physical conditions under which he or she works. A properly planned office will therefore take into account natural and artificial lighting and ventilation, temperature control, noise reduction, drinking water, lockers, toilet facilities, paint or decorative treatment, floor covering, and proper equipment and tools with which to work.

The proper and natural flow of the work through the office unit must also be considered. Back tracking of papers and excessive personal intercommunication reflect themselves in cost both directly and indirectly through retardation of the normal pace of office work movement. The office layout analysis will often point the way to improved work methods, allow for proper supervision, scheduling and control, and disclose shortcuts through elimination of work steps. It often brings to light excessive or outmoded equipment which is "eating its head off" in floor space consumption or reduction in individual or collective working efficiency.

It is assumed for purposes of this discussion that the building itself has been properly planned. It is also assumed that the planning of the organization as a whole has adequately taken into account the relationship of the various departments, both to each other and the organization as a whole. Most of the considerations which apply to the planning of an individual office unit will apply to the planning of the organization as a whole. Acting upon this assumption we shall consider the planning of a single unit only.

An Outline of the Technique of Office Layout. It is first necessary to record conditions as they exist. To this end an architectural floor plan should be secured. This should be to scale of one-eighth or one-fourth of an inch to the foot, depending upon the overall size involved. A print with white background is preferable. All partitions, doorways and equipment must now be carefully and neatly drawn in to scale. The designation of the various subdivisions should be shown. Desks, chairs, and files are readily recognized from outlines shown on the plan, other equipment not readily identifiable should be marked with its name, and sizes of all equipment should be plainly shown. It is considered standard practice to have all designations read either from the bottom or right-hand side of the drawing. The names of individuals or the names of their positions should be neatly marked upon the equipment outlines. Telephones, electric outlets, mechanical devices

requiring electric current should be shown on the master plan or on a copy of it. Copies of the master plan should be made by photographic or other process. One copy should be marked with the exact locations of existing ceiling light outlets with wattages indicated and locations of control wall switches shown. This copy can also be used to show all other electric current facilities available and also for such plumbing details as basins or drinking water fountains. If it is feasible to show all details upon the master plan, such a course is more desirable due to the interrelationship of all of these factors. Copies must be made however for the purpose of indicating work flow.

Work flow should be carefully studied and indicated upon a copy, or perhaps divided into sections and indicated on separate plans. Where the flow is complicated, it is desirable to make copies on transparent paper so that they may be superimposed. These data will form the basis of an analysis which should then be made as to how such work flow could be simplified or improved by changes in the layout.

If the planning involves the transfer of the unit to new area, an architectural plan of the new area should be secured. This should be to the same scale as the plan of the space to be vacated. If no move to other location is involved, another copy of the outline plan of the existing space should be secured. This copy should show only the fixed walls, columns, and partitions or other equipment which cannot or will not be moved or changed.

In either case, templates to scale should now be cut for all existing movable equipment. The templates should be cut from light cardboard or index bristol, preferably of a color which contrasts well with the background of the plan and photographs well, and in such a manner as to make any lettering on templates readable after photographing. Yellow or salmon is very satisfactory for this purpose. The templates must of course be cut to the same scale as the plan. They should be marked with the designation of the equipment, its size and the owner's name or identifying number. By mounting the plan upon a light board and using map pins these templates may be pinned over the master plan as a check to see that all have been accounted for. Having provided templates for all movable equipment, these may be laid on the plan of the new space or an outline plan of the existing space and various arrangements tried out. Based upon data developed in the previously described studies of work flow, the templet arrangements can be shifted about until the best groupings, both as to utilization of space and work flow, have been arrived at. The templates can now be pinned in place on the new plan. Photographic copies of this new plan can then be used for indicating electric outlets, telephone connections, drinking water, etc., and in connection with moving schedules.

Space Standards. A study of the above described plans and layouts, and an examination of the use to which space is being put will gradually allow for the setting of space assignment standards. While these standards, like all other good standards, must remain flexible they will point out that for a certain well defined job with its customary equipment a definite minimum adequate allowance of floor space is necessary. Standards of this kind simplify the planning and control problem in that they help to eliminate

wastes and furnish the basis of estimates of floor space required. A study made in 1930 by the National Office Ratios Committee on space standards and published in *System Magazine* for April, 1930, showed a wide variation of these standards. A study of this article will give a good idea of the factors involved and the possible savings which may result. The scope of this discussion does not permit a detailed examination or study of methods involved in arriving at or accepting such standards.

Inventory of Equipment. Many companies maintain an inventory of all equipment and have all such equipment tagged. Where this is not so, it is desirable to inventory and tag all equipment prior to moving it, so that the equipment may be accounted for after the move has been made and in scheduling it in and out and getting it set in its proper place. In connection with the inventory necessary at the time of the shift it is desirable to examine all equipment to determine which, if any, is inadequate, decrepit, or otherwise undesirable. Substitution or changes can then be planned for at the time the move is made.

Some Comments on Moving. It is obviously impossible to set down here all of the details which must be looked after in connection with a rearrangement or move of an office unit. Some general observations, however, may prove helpful. Careful planning is the first essential. A sequence schedule must be worked out to avoid confusion and simplify both the moving in and the moving out of equipment. Schedules for electrical work, plumbing, structural changes, etc., must be coordinated with the moving schedules. The movement of elevators, vans, etc., must be studied and fitted into the plan. Equipment which does not readily go through doors or into elevators must be spotted in advance and provision made for handling it. Weights of equipment must be considered both from a handling standpoint and also as to elevator capacity. The necessary personnel for dispatching and placing equipment must be organized and instructed. Such matters as these will determine whether or not the move is done quickly and without confusion or otherwise. It is safe to say, however, that all the time and effort spent on planning a move will pay generous dividends. And this, in fact, may be said to apply to the entire subject under discussion.

PLANNING AND SCHEDULING OFFICE WORK

BY EVELYN M. DAVIS, *Partner, Woodward, Fondiller and Ryan*

There are very few who have the opportunity of planning and scheduling office work for a new organization. The problem with which this section shall deal is therefore how to plan and schedule work for an organization that has been running for some time. It has been demonstrated that an organization which installs efficient central planning and controlling of its routine can save at least 20 per cent of its routine pay roll.

This subject will be treated under the following headings:

- A. The need for planning and scheduling office work.
- B. The creation of a planning and scheduling department.
- C. Special planning problems.

A. The Need for Planning and Scheduling Office Work.

The principal causes of department inefficiency are:

1. Plans do not keep pace with the growth and development of the organization.
 2. Changes are made in certain details of the routine without realizing how they affect the whole.
 3. Personality of the department head is allowed to control the growth of the department.
 4. Lack of definite knowledge by department head of each clerk's duties.
 5. Failure to select the right type of clerk for the job.
 6. Lack of standards of production.
 7. Lack of balance between units in the routine.
 8. Lack of control of routine of the department.
- A discussion of each of these points follows:

1. Basic Plans. When a company gets its routine plans under way, following a thorough reorganization of its plans, the executives usually heave a deep sigh of relief that the trouble is over. The executives, after having taken an active interest in the planning, leave their plans to be followed through by less able personnel. In a relatively few years the plan is outgrown and the executives are out of touch with the situation. Clerks and supervisors change the routine in which they are engaged, sometimes because they have misunderstood instructions, sometimes because they believe they can improve it.

In the premium crediting division of a casualty insurance company, premium cards are maintained for every policy in force and the payments are posted thereto as they are received. In addition, commission cards were maintained for each agent. The commission cards had been intended to control the premium crediting and the premiums were to be posted therefore independently to both records. It was found, however, that the clerks were crediting the premium cards currently and then at the end of the month copying in totals to the commission cards. Under their revised method, no control of the figures was obtained. The manager could not believe that such a thing had been occurring for three years without his having been aware of it.

Moreover, as an organization grows and volume increases, the management should review records to decide whether they are still of value. When a business is small the management watches details closely; as it becomes larger, the cost of collecting such data frequently outweighs its value. Furthermore, the specific information is often no longer of interest. Yet we find departments still maintaining records which have outgrown their usefulness. Often long hand methods are continued when the volume is such that machine methods would be more economical. After machines are introduced, plans should keep pace with the improvements that are made in these machines each year.

2. Changes in the Routine. No change in any part of a routine should be made unless it is authorized by someone acquainted with the entire procedure. The violation of this principle causes considerable waste in an organization.

The manager of a claim department wished to count the number of claims payments by territory so that each of his adjusters would be responsible for approximately the same amount of work. He could have obtained a rough gauge of what each adjuster was doing by keeping a record within his own department of the number of new notices in each territory. However, he decided it was easier to request the information monthly from the statistical department. The head of the statistical department happened to be an ambitious type who would have furnished any amount of information to anyone, so he readily assented. The extra work involved required an additional clerk in the statistical department.

A different type of waste was found in the accounting department of one company. The company had an elaborate Elliott-Fisher installation which analyzed its premium receipts by state, agents, etc. Several years later Hollerith machines were installed, and thereafter the statistical department furnished the monthly distributions. In spite of this fact, however, the Elliott-Fisher operators continued their columnar distributions when all that was needed was a total posting to serve as a control to the distributions of the Hollerith machines. The Elliott-Fisher division should have been reduced by 60 per cent.

3. Personality of the Department Head. Too often the personality of the department head is allowed to determine the value of the department and to control its growth. His influence on the department is felt in a number of ways.

First, there is the good-natured department head who gives in to all the other heads and who is willing to furnish them with any data or information, regardless of how much work is involved. Often the information is of temporary interest to the man who requests it, but long afterwards the other department continues to furnish it.

Secondly, there is the ambitious type who volunteers to undertake or suggests new activities and gets control of these activities through the forcefulness of his personality in selling the ideas, but is not careful to line up the cost of the activity with the benefits accruing to the company therefrom. This type causes a great deal of trouble in an organization, because he is not content with merely increasing his own department, but attempts to infringe on the activities of other departments. It is not intended to disparage the employment of enthusiastic, ambitious executives; it is merely pointed out that their activities require just as careful control as the slower working type.

A very capable woman who is in charge of the statistical department of a fire insurance company was unusually machine minded and began to devise ways and means of doing more and more of the accounting on the Hollerith machines. The head of the accounting department rebelled as he saw his hooks of accounts disappearing from his department, but as he was not as convincing a talker as the statistician, he lost his arguments at every conference. The result is that the bookkeeping is being done in a very ingenious manner in the statistical department, the accounting department has dwindled to almost nothing, while the company has gained nothing from the change. The system is working successfully, but it depends too much on a certain personality to be a safe procedure. It is a creation of the present

statistician; she is exerting all her ability to make it a success. If she were to leave there is grave doubt if the system would work satisfactorily. In any event, personalities should not have determined the procedure.

Frequently we have the opposite type of man, who never wishes to change any part of the routine of his department or to take on any new duties and who can always find reasons for his refusal.

Too often we find special jobs assigned to the department head in whom the manager has the greatest amount of confidence and who he feels will complete the task with the least help from himself, in spite of the fact that the routine is such that another department could handle it more economically.

It is therefore necessary for an unprejudiced person to plan the activities of each department and to assign specific jobs where they can be handled most expeditiously and most economically.

4. Knowledge of Each Clerk's Duties. A department head after a few years frequently forgets the details of his department and does not know what each clerk is doing. As the volume of work increases, therefore, he must rely on the individual's ability or willingness to handle more work within a day. Furthermore, if his department is given additional tasks, he will assign them to whichever clerk will undertake it with the least assistance or explanation from him. That is why we so often find clerks with an unequal amount of work assigned to them.

When the department head is not sure of the details, it means that the instruction of new clerks is left to some one less responsible. Wrong explanations are thus often given to the new clerk, and the routine soon grows away from the original plans. Some centralized planning authority should be given the duty of checking and correcting such trends.

5. Failure to Select the Right Type of Clerk. Frequently the wrong type of clerk is selected for a position and the department head is too lazy to replace her.

The misfits may be classified under the following headings:

- a. Lack of education necessary for a specific job.
- b. Wrong personality to work with the particular department head.
- c. Ability as an individual worker but no administrative ability.
- d. A mental worker in a job requiring mainly manual dexterity or *vice versa*.
- e. Unable to cooperate with the other clerks in the unit.
- f. Uncongenial work.

6. Lack of Standards of Production. Every department head should know exactly the volume of work handled by each of his clerks and should determine what is the standard of production to be expected for each type of work. It is surprising how seldom production records are kept and how seldom clerks are required to maintain a prescribed standard.

Unless standards of production have been set, it is difficult for the manager to obtain work from his clerks at their greatest capacity. On the whole, clerks will do what is expected of them. If the manager expects only 30 checks to be typed a day, the clerks will unconsciously slow down to that rate; if he requires 60 checks to be typed the clerks will type 60 checks. Of four policy typists each receiving approximately the same salary, one girl

typed 90 policies a day; the others averaged 40 to 50 policies. After an examination of the work it was decided that an average typist should complete 75 policies a day. One of the typists was transferred to other work, the salary of the girl who was typing 90 policies was raised and the other two typists were expected to type 75 policies a day. The result was surprising. They are all typing 90 to 100 policies daily. Of course, the simplest way would have been to pay them on a bonus basis, but in this particular instance the management did not care to do so.

An analysis of the number of claim checks typed daily showed that the average was 30 checks per typist. The average should have been about 75 checks. After watching the work it was obvious that one of the typists was doing practically nothing; it was recommended that she be eliminated, but the manager insisted he could not do without her. The typists were therefore required to initial the carbons of the checks, and a record of the individual performance was kept. The typist in question showed a record of 6 checks one day and 10 to 15 each of the remaining days. The record therefore settled the argument. Centralized planning and centralized control are the best means of assuring the correction of such situations.

7. Lack of Balance between Units. It is necessary for the routine to be so organized that each step proceed at the rate of speed desired for the most effective functioning of the department, or as between departments, that the rate of speed be that giving the most effective results for the business.

Inspection of the policy routine in an accident and health company discovered that the work halted at the assembly desk. At this point the riders, photostats, etc., were pasted in the policy, and all were numbered. The two clerks engaged in this process were below the average. The result was that the work was halted at this desk, with results detrimental to the proper functioning of both department and business.

8. Lack of Control. The fundamental principle of controlling production in a clerical department is just the same as for the control of other products, viz., that who-ever is responsible for the work should know:

- a. The volume of work received every day.
- b. The rate at which the work is completed.

This record is the most important record that can be furnished to an executive and without it a department lacks the incentive to push ahead.

The results of such control sheets installed in the policy department of an insurance company are worth relating. The function of the policy department is to issue new policies. The management had received complaints from time to time from the agents in the field that too long a time elapsed before they received the policies; this delay often resulted in their losing the business. No one had any exact information, however, as to the time elapsing between the date the application was received and the date the policy was mailed, and there were no records on hand to furnish this information. An application register was installed and every application was numbered as it was received. The department head then made a weekly summary to show the percentage of the policies issued by the end of the first day, by the end of the second day, etc.

The reports showed that the situation was more serious than had been realized. Only 1.8 per cent were issued the same day as received; 2.8 per cent were issued by the end of the second day; 3.6 per cent were issued by the end of the third day; 7 per cent by the end of the fourth day, and 13.4 per cent by the end of the fifth day. Experience had shown that at least 30 per cent should be issued the same day and 70 per cent by the end of the second day. About 20 per cent of the applications received are held for several days awaiting further information.

The problem was, therefore, to increase the efficiency of the department so as to enable it to issue policies as promptly as its competitors. Its weakness was one of administration and the situation was corrected by installing control sheets at the critical points in the routine. Without the control sheets it would have been difficult to detect the points at which the delay was occurring. It was found that the speed of the routine was dependent at two points upon other departments, and control sheets were immediately established to register the elapsed time in the passage of the work between these departments. The clerks in the department take a keen interest in the records shown by the control sheets. Since they fix the responsibility for any delay, each one is anxious to complete her part as quickly as possible. Without the control sheets, the efficiency of the department is not known, but is dependent upon impressions and prejudices.

The following table shows the progress in efficiency. The change was effected in a week early in March, 1930. In addition to the progressive improvement in speed, it was possible to reduce the number of clerks from twenty-nine to twenty-three.

PROGRESS REPORT

Percentage of Applications on Which Policies Were Mailed by the End of Each of the First Five Days

Period	Number of applications received	Policies mailed				
		Same day	2d day	3d day	4th day	5th day
November, 1929.....	2,690	1.8	2.8	3.6	7.0	13.4
January, 1930.....	2,484	1.6	4.5	13.2	37.4	61.7
February, 1930.....	3,574	1.2	9.7	41.3	70.5	81.5
March, 1930.....	3,701	9.6	48.9	76.0	81.3	82.4
April, 1930.....	3,212	21.5	65.7	76.9	78.6	79.9
May, 1930.....	4,146	22.1	55.5	75.2	80.3	81.6
June, 1930.....	3,671	19.6	64.3	77.6	83.4	84.8
July, 1930.....	2,863	31.3	73.2	80.6	81.9	82.6
August, 1930.....	3,263	30.1	71.9	79.4	80.9	81.3
September, 1930.....	3,162	32.1	71.7	76.2	76.9	77.3

B. Creation of a Planning and Scheduling Department.

In the following outline of the formation of a planning department, recommendations are made as to organization, selection of personnel and training required for effective work.

Organization. The work of a planning department divides itself into three phases:

1. Planning.
 - a. Methods.
 - b. Routine.
2. Personnel.
 - a. Selection.
 - b. Training.
 - c. Development.
3. Control.

Where the company is large enough these should be organized as separate units, the control being installed and subject to review by the manager of the department. In general, the planning and personnel will have to be handled by different people. The qualities needed in an efficient organizer are entirely different from those required for selecting, training and developing the personnel, and are not frequently present in a single personality. In fact, the development of proper plans and suitable personnel is not always recognized as two distinct problems requiring different personalities to control their development, yet needing unified action under the direction of the manager, if the best results are to be attained.

The controller of a large life insurance company who has been responsible for cutting down company expense provides a good illustration. With a good engineering background, keen analytical ability, and a shrewd ability to plan, he makes the most of the latest office appliances and is adept in installing short cuts. But he never sees a problem in terms of the people with whom he has to work. When he tries to put his plans into operation, therefore, he is frequently met with opposition which he is helpless to handle because he does not understand it. No matter how clever the plans are, if the right type of people are not selected to carry them out, or if the planner does not know how to win their cooperation, only a part of the desired result is obtained.

As indicated above, if the organization is large enough the manager will be responsible for the controls. Otherwise, this function should be undertaken by the supervisor of the planning section. The object of the controls is to determine that the plans are being carried out economically and on time, and to detect any weaknesses in administration before they become costly.

1. Planning Unit and Control Unit.

a. Qualifications for Supervisor. The supervisor should be familiar with the requirements of the business in all departments, and the relative importance of each requirement. For example, he should recognize types of work where economy of operation is subordinate to speed of operation, or when accuracy is more important than speed. He should understand the interdependence of departments, and what is more important, appreciate the home office needs of the field or sales force.

The supervisor should be capable of commanding the respect of the department heads for his knowledge so that in time they will come to him voluntarily for aid. He should know how to approach the clerks so as to get the necessary information and suggestions from them. He should have patience to be willing to let things work out gradually so that changes can be made with the least disturbance. He should have the analytical ability to break down the most complicated procedure into simple steps which form its elements. He should have creative ability and imagination, so that he can see the possibilities in new machines and new suggestions and apply them to his own problems. He should have the will power to push ahead when he finds reluctance to change; the courage to persist in the face of unpopularity; the ability to keep out of all office politics. He should be able to command the confidence of the officers to effect the changes he recommends.

b. Training and Organizing for the Position of Supervisor. In starting with a company in this capacity, it is usually necessary for the supervisor to undertake the following steps:

1. **Writing an Office Manual.** The supervisor should write the procedure being followed in each department. It is important that this be done in the natural order of the flow of work, as he goes from one department to another. The specific duties of each desk should then be determined.

2. **Suggested Changes in Methods or Routine.** After the supervisor has studied the existing procedure, he can recommend changes in the methods or procedure. The approval of the department head must be obtained to all the recommendations.

3. **Writing the Revised Office Manual.** A revised office manual should then be written to incorporate the changes that have been approved.

4. **Standards of Production.** Standards of production for the various operations should be set up.

5. **Duties of Each Desk.** The routine for each desk should then be established, based upon the volume already determined as the average production to be expected.

6. **Approval of Forms.** The forms should be studied, simplified and fitted to the revised procedure.

7. **Selection of Personnel.** At this point the supervisor of the personnel section should be consulted for recommendations as to any changes in personnel.

8. **Installation of Controls.** Control sheets should be devised which will fix the responsibility at the critical points, will show the management the rate of production, and will bring to light weaknesses of operation as soon as they occur. These control summaries should be furnished weekly to the manager.

9. **Employee Production Records.** Individual performance records should be maintained as a basis for salary increases.

c. Responsibilities. He is responsible for becoming acquainted with the latest office appliances.

He is responsible for keeping in touch with the latest management principles, through organizations, reading and visiting other companies.

No change in any details of the existing procedure should be made without his approval.

No new work should be undertaken without his analysis of the necessity, the value to be obtained and the cost of the additional work.

No additional clerks should be hired unless authorized by him.

2. Personnel Unit.

a. Qualifications for Supervisor. The applicant for this position should be one who is familiar with the requirements of the business, so as to understand in general terms the duties of each desk and the relative importance of the various jobs.

He should have a good background in psychology; like people; have in particular the ability to talk to the clerks on their own level and yet at the same time the ability to command their respect; be able to be sympathetic without becoming too friendly; be able to judge people by their merits and not be influenced by hearsay or by the opinions of others. He should have the courage to give his opinion about the clerks regardless of the likings of the department heads or officers. He should know how to criticize without offending, how to praise without flattering.

b. Training and Organizing for the Position of Supervisor.

1. Getting Acquainted with the Personnel. Each department should be visited and the clerks interviewed, so that the supervisor becomes acquainted with each clerk. Eventually he should know them well enough to be aware of their outstanding abilities and main weaknesses.

2. Learning the Duties of Each Desk. The supervisor should learn the duties of each desk in a general way so that when a vacancy occurs he can select the candidate who can handle the work efficiently.

3. Getting Acquainted with the Department Heads. The supervisor should know the department heads so as to be able to select clerks who will work harmoniously with them.

4. Learning the General Rules. The supervisor should acquaint himself with the general rules of the office as to lateness, vacations, salary increases, pension plans, etc.

5. Personnel Records. The supervisor should install personnel records to fit the requirements of the particular office.

c. Responsibilities. He will be responsible for the selection of personnel to fill any vacancy, subject to the approval of the department head; recommend candidates for transfer when they are misplaced or have reached the maximum salary; recommend candidates for new positions that are created; settle personnel difficulties arising between clerks and department heads; be consulted on salary increases; help the clerks to solve any personal problems which they may have; make recommendations to the management for any required personnel policies.

C. Special Planning Problems.

Coordination between Departments Where a Central Planning Department Does Not Exist. There are many organizations in which a central planning department does not exist. In order to obtain co-operation between departments, the manager should hold monthly meetings of his department heads to discuss their respective problems and to help each one to gain a knowledge of the other's needs. The success of these meetings depends entirely on the personality of the manager. He must be well enough acquainted with the problems of his departments to lead the discussion as he is the only one who can see the organization as a whole. Unless he commands the situation, personal feelings will creep in, the discussions will center around the department

which has the strongest head, and the weaker department heads who need the help most will remain silent. A program should be planned in advance by the manager.

Planning All Classes of Work. All classes of office work can be planned and scheduled by a specialized unit. Theoretical and technical workers usually think that their work cannot be organized. This is not true, and furthermore this type of worker needs the most help. The technical workers will probably have to furnish an outline of their work, but the specialized unit can lend them the benefit of general rules of organization.

Reports and Statistical Data. The preparation of operating figures and reports, accounting reports and statistical data can be speeded up by planning and scheduling. In order to compile a report it is often necessary to obtain information from a number of different sources. Unless the various units supplying the data can produce their information at the same time, the report cannot be completed. An important executive report is often held up for days because one unit has failed to supply its part. Perhaps the other units have worked overtime and their effort is thus wasted.

Planning and Scheduling without Bonus and Incentive Plans. Accurate scheduling can be obtained without the aid of bonus and incentive plans. Most clerks take a pride in accomplishment. The selection of the right personnel, together with the personality of the department head which shows leadership and wins cooperation, will obtain as lasting results as any specialized form of payment.

Rush Orders. Rush orders should be investigated and reduced to minimum. They arise sometimes from necessity, but more often because of inefficiency or wrong perspective. A head of department in an insurance company persuaded all the service departments such as mailing room, Photostat Department, etc., to handle her work as rush orders. The system relieved her of having to exert any pressure on her own clerks. We are all acquainted with the department head who never starts his reports on time and then always rushes the stenographic department or requires them to work overtime. Where rush orders are found to be necessary they should be handled without interfering with the regular routine. Sometimes a utility section can be utilized for that purpose. Careful planning and scheduling will eliminate most of the rush orders. As a rule, the work of the service departments should be handled in the order of receipt. When a department head insists, however, that his work must be rushed through and asks that other work be halted for him, the supervisor of the service department should consult the manager as to the value of each requirement. Each department head understands the need for his own work only, and the manager must determine the priority.

The Peak Load Problem. Fluctuations in the amount of business coming in are handled in different ways. The classic example of that problem is in the Massachusetts companies who write compulsory automobile insurance. On account of the compulsory law they have to write most of their policies Jan. 1, or Apr. 1.

The best way to handle the situation is to organize the work in such a way that the part that requires technical knowledge is handled by the permanent

clerks and the routine work can be undertaken by the staff of temporary clerical workers. In one company in Boston where such a problem existed, each of their policy typists had not only to type the policy but had to look up the rates in the automobile manual and calculate the premium. During the peak load period it was not possible for temporary clerks to do the job correctly. The solution was simple—the routine was divided into two parts:

1. Selection of rates and calculation of premium.
2. Typing the policy.

It was possible thereafter to hire temporary clerks to type the policies. All the permanent clerks were instructed in the rating routine.

THE CONTROL OF OUTPUT IN OFFICES

BY WALLACE CLARK, *Wallace Clark and Company*

The control of output is the chief responsibility of the executive in charge of an office. He may be able to write more letters and better than any of his subordinates, he may be an expert in the handling of orders or the preparation of reports, but that is not the kind of ability which distinguishes a good office manager. The reason for putting him in control over other men is because of his ability to get work done.

In the dark ages of management the method of getting work done was through fear. The manager's favorite weapon was threat of discharge and he depended on fear of loss of income to stimulate his employees. Fortunately this primitive type of management has become the exception rather than the rule.

During the last decade emphasis was placed on stimulating production by paying employees according to the amount they produced. This point of view is also changing and managers today regard it as merely a matter of fairness to reward those who produce more than the average. This change is a shift of emphasis from increasing production to simple justice to men.

The interest of management is now focused on a third method of getting work done, that is, removing obstacles which prevent workers from doing their best. This method is based on the belief, first, that all employees *want to make good on their jobs*, and, second, that it is the *task of the manager to help those under his control to make good*.

The better understanding of man and his mental processes, brought about by the discoveries of modern science, has rendered untenable the old idea that it is natural for a worker to shirk. We have learned that his desire to create, to reap the benefits of his toil, and to think well of himself, is more powerful than his propensity to soldier. We therefore know that if a man does not do a fair day's work, it is not due to anything inherent in his nature, but to some other influence.

The manager of an office accordingly desires to find out what influences make it difficult for an employee to make good on his job or, in other words, the obstacles which prevent him from doing a fair day's work, but he is often uncertain as to how to go about it. Shall he make frequent trips through the office, talking to the various department heads and all of the employees under

their charge? If the office is large it will be impossible to make the rounds often enough to keep in touch with conditions, for serious troubles are seldom on the surface and a few moments' conversation will not reveal them.

It is obvious that a manager cannot diffuse his energies in this way and must have some method or procedure which will automatically bring to his attention those conditions most seriously interfering with the desire of his employees to make good.

A Method of Locating Obstacles. The first requirement of such a method must be, above all, to indicate movement. Nothing in modern industry is static. The work of an office or manufacturing plant is composed of moving forces. Sales, production, stocks on hand, and prices are never stationary for long at a time—there is a continual ebb and flow and the movement of each has an influence on the others. It is comparatively easy to note the movement of work through a shop by following the material in its progress from one operation to another, but in an office it is more difficult. To a casual observer there seems to be only a multiplicity of papers drifting from one place to another, yet it is these papers, either forms or letters, which represent work—in fact, they are the only tangible evidence of it.

In every office there are two main streams of work with many tributaries. In a company which both manufactures and markets a product, one of these streams flows from the customer through the sales force and the office to the plant, while the other stream flows from the plant through the same channel to the customer.

It is the task of the office manager to control the movement of these streams of work. Orders, for instance, must come in and go straight through instead of wandering around and possibly finding a permanent resting place in some pigeon hole.

In order to establish an effective control of output the office manager must:

1. Measure the rate of flow.
2. Compare that rate with what has been decided upon as a satisfactory rate.
3. Find out what retards the flow of work and remove the obstacles.

Control in an Order Department. The application of this procedure to an order department may be taken as a concrete example. The office manager studies the work with the head of the department: orders of only one type are handled; they are translated into shop terms, checked for completeness and accuracy, and typed on sales order blanks. The orders received average 100 per day and the department is provided with the requisite number of employees and the equipment necessary to handle this volume of work.

The office manager asks the department head to send him a report at the end of each day giving the following information:

Number of orders on hand at beginning of day.
Orders received during day.
Orders put through.
Orders left over at end of day.
If 100 orders were not put through, the reasons why.

It will be seen that this daily report shows the actual rate of flow in the "number of orders put through," the desired rate in the figure 100, and the obstacles which prevent the attainment of the standard enumerated as "reasons why." In the "Orders on hand at beginning of day" and "left over" the office manager can see whether work is piling up or decreasing and can accordingly add employees to the department or transfer them to other work.

In such a daily report there is presented to the office manager the salient facts in regard to the progress of work through one of his departments. If that progress is not satisfactory when compared with a predetermined standard, the obstacles are automatically brought to his notice. He is thus enabled to concentrate his attention on the things which most seriously interfere with the daily work of those under his control.

Similar reports may be secured from other parts of an office. When there is a receiving department separate from the stockroom, it is the task of the person in charge of it to receive packages and deliver them to their proper destinations in various parts of the office. Accordingly his daily progress report would be as follows:

Packages on hand at beginning of day.
 Packages received.
 Packages delivered.
 Packages undelivered at end of day.
 Reasons for non-delivery.

Stenographic Department. In controlling the work of a stenographic department it is the aim of the person in charge to get into the mail each night all the letters dictated during the day. Accordingly the report of a head stenographer would be as follows. In this case actual figures are used:

Number of lines on hand at beginning of day	180
Lines dictated	2,504

Total	2,684
Lines finished	2,624

Left over at end of day	60 lines
-----------------------------------	----------

Reason for work left over: Mr. Black dictated ten letters after four o'clock.

It is obvious that there will be many reasons for such work being left over: a typewriter might be out of order; one or more stenographers absent; dictation given too late in the day; an unusual amount of work; not to mention a variety of things which interfere with individual output. These are the things which the head stenographer needs to bring to the attention of the office manager, for, if they are left to occasional reports in conversation, little will be done to prevent their recurrence.

Filing Department. There are certain parts of the office where it is burdensome to report on all of the work done, as in a Filing Department, where it would require too much time to count all of the papers filed. In this case the daily report would show how many papers are unfilled at the end of the day.

These may be divided into orders, correspondence, reports, etc. and the reasons shown separately for each division.

The examples given will serve to show the form which these daily reports of progress take and it will be easy to understand how the method may be applied to the work of correspondents, of traffic, purchasing and mailing departments, the supply stockroom, and even to the janitor, house carpenter, painter, electrician, and other employees engaged in the maintenance of an office building.

Charting the Progress of Work. Where the office is large and the manager has a good many departments to look after, he will find it burdensome to go over all of these reports each morning and will have one of his assistants enter them on a Gantt progress chart. Such a chart covers a two-week period; the different departments or divisions are listed on the left side and each morning the information contained in the daily reports is charted, the daily space representing what should be done in a day, lines showing the actual performance, and the reasons for falling behind being indicated by symbols.¹

On a single sheet of such a chart the office manager notes the progress made in every section of his office and his attention is directed to those parts of the work which are least satisfactory. He is thus enabled to make the best use of his time and to maintain a more effective control over the output of his office than is possible without some such method of promptly getting at the facts in regard to movement of work and the obstacles which interfere with its progress.

Kinds of Obstacles. It was stated at the beginning of this paper that the chief responsibility of the manager is to control the output of his office and that the best way for him to do this is to help those under his control to make good. Daily reports of progress were then outlined, which throw into high relief those things which prevent employees from doing a fair day's work. Let us now consider the problems which confront him in his attempt to remove these obstacles.

The manager finds that many delays are caused by things which obviously should have been avoided by the management: appliances or furniture may be in need of repairs or not suited for the present purpose; working conditions may be unsatisfactory; information received from other individuals may not be accurate or conveniently arranged; instructions may be incomplete; or there may be interruptions. These obstacles and others of the same nature occur frequently, but once they are known to the manager, no great difficulty is encountered in their removal.

When lack of progress is due to the physical condition of employees, remedial measures are taken, but it is somewhat more difficult to get at the obstacles in the minds of individuals.

An employee may be incapable of acquiring the necessary knowledge to do the work assigned to him. This often happens even if care has been taken to test his mental capacity before he was employed. On the other hand, he may be capable but without the necessary training. His work may not be sufficiently interesting to hold his attention.

¹ See Progress Chart of Office Work, "The Gantt Chart," by Wallace Clark, p. 96, Ronald Press Co.

An employee may think that his job is not good enough for him and that it belittles him in the eyes of his associates. He may be dissatisfied with his present position because it does not seem to give him opportunity for development or lead to promotion. He may feel that his wages are not commensurate with the importance or amount of work he does. It is true that the average person is more interested in development and promotion than in wages, but he resents it when the firm profits by his development and does not share with him.

An employee may be worried because he does not feel secure in his position. He may be resenting criticisms which he believes to be unfair. When unskilled laborers resent the treatment they get, they throw down their tools and quit work, but an office employee does not react in the same way. He goes on with his work, at least to all outward appearance, but his mind is occupied with other things and work immediately decreases in volume and errors multiply.

The attention of an employee may be distracted by events in his life outside the office.

Removing Mental Obstacles. The manager knows that mental attitudes cannot be changed by official orders, and that in order to alter conditions of mind which slow down individual output, he must understand some of the more positive sides of the natures of employees to which he can appeal. A young man is particularly interested in increasing his earning power and will grasp eagerly at anything which he believes will help him. The chief interest of an older man, on the other hand, is in maintaining the position and income which he has already attained and he will welcome anything that will increase his security. There is no age limit separating these two kinds of men—when a man loses interest in increasing his earning power and fixes it on security, he is no longer young.

Those women who are in business only for a few years seem to be most interested in their present incomes and in pleasant working conditions. Those who are in business permanently may be appealed to on the same grounds as men.

The average office employee, at least during the first few years of his business life, likes variety in his work. It is true that there are some who prefer monotonous tasks, which leave their minds free for reverie or day dreams, but in such cases it is better not to indulge this propensity. A manager should therefore provide variety in the tasks assigned to employees and infuse into them as much interest as possible.

An office worker has "a taste for effective work and a distaste for futile effort." He likes to see the results of his work and is always interested in knowing the part which his routine plays in the business as a whole. As a rule the more he knows about the history and aims of a company, the more pride he takes in his work.

Office workers are usually ambitious to learn more about business and to hasten their advancement into positions of responsibility. A wise manager therefore takes pains to stimulate the ambition of his subordinates by discussing with them their future plans, the special knowledge they will need and where it can be secured. Promotion is, of course, the greatest stimulus

to ambition, although it is sometimes as effective to tell an employee frankly why he cannot be promoted.

When changes are contemplated, the manager does not wait for records of low production to indicate that an employee resents the change, but before the new method is installed he points out to those affected how the changes will benefit them. He knows that most of them are in the office because they have to earn a living and that it is natural for them to think first how a certain thing will affect them and secondarily how it will affect the company. A manager finds his employees only mildly interested in the amount of money the firm will save by the adoption of any method, but, when he convinces them that they themselves will be benefited, he meets with interest and cooperation.

One of the great sources of satisfaction to a human being is the creation of something new or the development of something better than has existed in the past. Understanding this the manager develops initiative in those under his control by encouraging them to go ahead and do things on their own responsibility. He knows that they will get some things wrong, but every mistake, if handled properly, means a distinct advance and each constructive suggestion received from an employee indicates an active mind concentrated on his work.

In making out daily reports of progress such as have been described, workers place in the hands of the one to whom they are responsible the key to their minds. If this information is used to drive them, no beneficial results will be secured, but if a manager believes that it is his task to help employees to make good and concentrates his attention on locating and removing the obstacles which stand in their way, work will be done on time, quality and accuracy will be improved, costs will be low and employees will be contented and interested, in short, he will have developed an effective method of controlling output in offices.

METHODS OF COMPUTING AND CHARGING OFFICE COSTS OF OPERATION

BY H. J. TAYLOR, *President, The Club Aluminum Co.*

In many large offices the only costs of operation accumulated are total periodic figures covering operating expenses. These figures give the office manager and other company executives information as to the total of payroll, rent, depreciation of equipment, miscellaneous overhead, insurance, telephone and telegraph, and other expenses. If the total of these expenses has decreased from period to period, the office manager knows that a reduction of total office expense is being made. However, he does not know in what particular units the economies have been effected. It is quite possible that some units are operating at a greater expense, while extraordinary economies are being effected by other units in the office. Unless some means of measuring the operating costs of the individual units in the office is devised, it is impossible to give credit where credit is due. It is also not possible for the office manager to know in which units operating expenses are increasing in

order that he may be able to analyze the work of these units, and make an effort to reduce expenses.

In measuring the results of the work of any individual unit in an office two things must be taken into consideration. First and foremost is the efficiency of the unit as expressed in the type and effectiveness of the work turned out by the unit. The particular unit under consideration may have charge of field work, and the effectiveness of the work of the unit is, therefore, measured in the results shown in the field work under its supervision. If it happens to be a sales division, the effectiveness may be measured in volume of sales. If it happens to be the distribution division, the effectiveness may be measured in stock turnover and reduction of inventories. The other factor that must be considered in arriving at the efficiency of the unit is the cost of performing the particular work which the unit has assigned to it.

For instance, it is quite possible that an office unit might double its working force and, as a result, show an increase in the effectiveness of its work in the field. However, when the increase in the costs of operation of the office unit is taken into consideration, it may be that net economy has not been effected. On the other hand, if the office sales division is able to increase its effectiveness in the field as shown by increased sales volume and at the same time lowers the cost of operating the office unit, it is quite evident that the unit has increased its efficiency at reduced cost.

Briefly stated, the reasons for calculating and distributing figures as to the cost of operating the respective units in the office might be as follows:

1. In order that office executives may have information as to the economy exercised in the various units in the office and thus be able to reward in a fair and equitable manner through promotion in rank and salary increases those unit heads and individual members of units who have been responsible for increased efficiency at a decreased cost.

2. In order that each unit head may know exactly what the cost of operating his respective unit is and, also may be able to measure in this manner the results and effectiveness of the work of his unit in terms of its cost.

3. In order that an effective control of the cost of operating the office may be effected, and that figures accumulated may be used in budgeting the cost of operating the various units in the office.

Control of Costs in Jewel Tea Company's Office. Table 1, which is the control sheet used to distribute the various costs of operation among the respective units, shows at the head of the columns the different classifications of the costs of operation.

1. One will note that the different departments and the units in these departments are listed in the first column on the left-hand side of Table I.

2. In the second column are listed the *payroll charges to the various units*. The payroll charge for each unit is taken from the payroll figures which are compiled in the payroll unit, in accordance with a list of the employees working in each unit and the length of time each works during the period. The clerk in charge of the "cost of operations plan" accumulates the time worked by each worker in the respective units from the assistant office manager who controls placement of personnel in the office. A form is used

by the assistant office manager for informing the clerk in charge of the cost of operations plan as to transfers, releases, or employment of office employees.

3. In column 3 on the control sheet are placed the charges for *space occupied* by the various units in the office. To determine the charge applicable to each unit for space occupied, we first reduce the total periodic rent to a cost per square foot. The amount of space occupied by each unit is determined, and this figure is multiplied by the square foot rental. The result is a periodic charge to the unit for space occupied. In case a unit makes a reduction in the number of workers, the unit is released from the charge for the space occupied by the desk at which the worker sat. If this space is not immediately assigned to some other unit, it is carried as a charge to a unit specified as "general." The total of the charge for space to general then gives us the total charge for space not being utilized in any one period.

The various units of the office naturally try to economize as much as possible on space, but in order to avoid a "cramped" condition in any unit, a minimum of four feet for aisle space back of each desk is required. As each unit head knows exactly what the cost of the space occupied by his unit is, we have found that the unit head is very much interested in utilizing the space used by his unit to the best advantage.

4. Column 4 in Table I shows the charge against each unit for *depreciation of equipment*. These figures are determined by ascertaining the value at which equipment used by each unit is carried on the chattel ledger in the general accounting unit. By use of the company depreciation charge of one per cent per period, we then determined the charge to be made. When the plan was put in operation, a complete inventory was made of the capital assets in the office and each unit head was given a statement of the equipment charged to his unit. The clerk in charge of the cost of operations plan keeps a record of all equipment, and is informed by the assistant office manager on a form provided for this purpose of any transfers of equipment from one unit to another, or of equipment sold or junked. The assistant office manager also informs the cost of operations plan clerk of placement of all new equipment received in the office.

The unit head is held responsible for the condition of the equipment assigned to him. His tendency is to see that good care is taken of the equipment in the unit, in order that it will not become worn out and require replacement. If new equipment is required before the old has been totally depreciated on the books, the unit will be charged with the loss on the old equipment as well as with depreciation on the new. The tendency is also to be careful in requisitioning new equipment. The unit head naturally does not wish to have the charge of depreciation increased and, therefore, will not requisition equipment unless he feels a real need for same.

5. In the Jewel Tea Co., Inc. office we have a central stenographic unit and have an installation of fifty dictating machines. There are nine transcribers in the central stenographic unit and three typists. The *charges for transcription of correspondence* and other material dictated through the dictating machines are distributed in column 5 on the control sheet. The central stenographic unit is considered as any other unit in the office in accumulating costs of operation. The classification of the cost of operating

the dictating machine and typing units is shown on line 36 of Table I. Dictating machine transcription charges to the various units are based on a cost per line unit basis. The entire production of the dictating machine unit is divided into the total cost of operating the unit for the period and an average cost per line is arrived at. The number of lines of dictating machine work transcribed for each unit during the period is then multiplied by the average cost per line and the total amount to be charged is thus ascertained.

The distribution of the charges for dictating machine work to the various units has resulted in a very marked reduction in the volume of lineage of the various units. The reduction is obtained mostly by a decrease in the length of the letter, but some of it is attributed to discontinuance of unnecessary letters, some of which were written before units were charged for transcription.

In order to assist the unit head in reducing dictating machine transcription charges, we have prepared figures which show the efficiency of the various dictators in dictating. This information is accumulated by arriving at the time necessary for the transcriber to transcribe the dictation of the various dictators. The dictators are then listed according to the degree of cost for transcription, and the unit head is given information as to the rating of the various dictators in the unit in the efficiency of their dictation.

6. The *typing charges* are shown in column 6. These charges are for typing which cannot be charged on a line basis such as form statistical reports or financial statements. A cost per hour is computed in the same manner as is used in computing the charge for computing work, namely, by accumulating the number of hours used during the period on typing work and the total charges for the typists who perform the work. As the typists are in the central stenographic unit, the periodic charges for the operation of this unit are combined with those of dictating machines as shown on line 36 of Table I.

7. The *charges for computing work* are shown in column 7. All computing work is charged on a time unit basis. At the close of the period, we determine the number of hours during which the several operators worked. The total number of hours worked during the operating period divided into the total cost of operating and computing units, gives us the average cost per hour for computing work. This average unit cost multiplied by the number of hours of work done for each unit gives us the charge for computing expense to each unit in the office.

The economy and efficiency of the central stenographic and the computing units are measured in a different manner than those of the other units in the office. In the case of dictating machine transcription work, we measure the efficiency and economy exercised by the average periodic cost per line of the work turned out by the unit. If the average periodic cost per line decreases we know that greater economy and efficiency have been exercised in the operation of this unit. We have the record of each operator covering her daily line production. We, therefore, know approximately how much each operator contributes to the economy effected by the unit.

The efficiency of the computing unit is measured by accumulating results on specific jobs. We have uniform branch records on which the same amount of computing work is done periodically. By keeping a record of the number of these forms assigned to each operator and to the computing unit

as a whole on these jobs, we are able to arrive at the approximate efficiency and economy exercised by the group and by each operator. On account of the fact that so many different types of work are done by the computing unit, it is at present not possible to use a better method of measuring the unit cost of work done in the unit other than the average per hour cost for work done.

8. In case a unit releases a worker for work in another unit or in case work which is normally assigned to a particular unit is done for that unit by another unit, a debit and credit charge is made on the cost of operations control records to cover the *interunit work* done. These charges are shown in column 8 of Table I. It will be noted that some of these charges are listed in red and others in black. The red figures are credits for work done for other units and the black figures are debits for work done for the unit by another unit.

Figure 1 shows the form used in accumulating information on the interunit work done in the office. This form is self-explanatory.

FIG. 1.—Interunit work.

The unit cost of interunit work is arrived at by dividing the total number of hours worked by the members of the unit into the total cost of operating the unit. In this manner we arrive at an hourly unit cost of work for each unit in the office. Since we have given credit for interunit work we have found that considerable saving is made by the unit head having an incentive to release any idle worker for work in other units. As shown on line 39 of Table I, the total interunit work for the four-week period was \$333.11. It will be noted that the debit and credit charges in column 8 for interunit work balance. We have found that interunit work, which was practically unheard of in the office before we installed the cost of operations plan, has now amounted to a figure more than equal to the total cost of handling the cost of operations plan.

9. *Overhead expenses* are charged to the various units in column 9 of Table I. Overhead expenses are indirect expenses for items such as light, heat, water, equipment, repairs, telephone, telegraph, exchange, and postage. Charges for overhead are computed on a basis of the square feet occupied by the various units as compared with the total office space. In other words, if one unit occupies 10 per cent of the total space and if the total "overhead" charge for the entire office is \$1,000.00, the charge applicable to this unit would be \$100.00. Any decrease in space occupied naturally brings about a decrease in overhead expense.

10. *Charges for supervision* are shown in column 10 of Table I. Supervision charges are computed in the following manner:

The total "pay roll" as charged in column 2 is subtracted from the total of the executive and general office payrolls. Fifty per cent of this figure is then arbitrarily considered to be the amount that should be charged to "supervision of the home office," the balance being arbitrarily set for "plant and field supervision." This amount is then divided among the various units in the office in the ratio of

- a. The average salary paid to the worker in each unit to the average salary in the entire office.
- b. The number working in each unit to the number working in the office.

In other words, the factors of the number working in each unit and the average salary paid in each unit are used in determining the charge to each unit for "supervision." While the total amount which we distribute to "office supervision" is an arbitrary amount, we believe that we have arrived at a fairly equitable manner of distributing the arbitrary figure. By decreasing the number of employees working in his unit, the unit head automatically decreases his "supervision charge" as well as the charges for pay roll, space, overhead, and depreciation of equipment.

11. In column 11, are placed the charges for *space occupied with files* in the Chicago plant by the respective units. This charge is made on a basis of the number of square feet occupied by the files and the total of these charges is equal to the charge in "general accounting" made by the plant against the home office for the total space occupied by home office files.

12. Column 12 shows the *total periodic charge* against each of the units in the office.

On lines 10, 19, 25, and 34 are shown the *total costs of operation* for the respective departments in the office.

13 & 14. The *economy effected by the various units* in the office is arrived at by comparing the base as shown in column 13, with the total cost of operation as shown in column 12. The difference of these two figures is placed in column 14. A red figure designates that the unit has operated at a total cost of operation above the base figure. A black figure designates that the unit has operated below its base during the period under consideration. The base is arrived at by taking the average cost of operation during previous periods. For instance, the bases for the last six periods of 1926 are arrived at by finding the average cost of operation for each unit during the first seven periods of the year.

15. In column 15 is placed the accumulated amount of operation cost below or above the bases of each unit for the operating year up to and including the current period. The total of column 14 which amounts to \$1,737.51 equals the total economy effected by the office during the current four-week period while the total of column 15, which amounts to \$7,370.82, represents the accumulated total amount for which the office has been operated under the bases as set.

Date Aug 25 1926

To: Office Manager

Information, statistics, or records, which have formerly not been part of the regular routine of the Dept. of Number 8 unit have been requested by John Brown of the Dept. of Number 1 unit

The following is a description of the work, including its source, how it is accumulated, and its purpose. Procedural Preparations of report which will show record of total purchases - by branches - stems purchased - cost source form - Temporary report for 3 periods ..

Is proposed work to be transferred from another unit, or is it entirely new? _____

If transferred, from what unit? _____

(weekly)

Estimated time for doing the work (periodically) 45 hrs. min.

Signed John Doe

Head of the unit which is to do the work, if approved.

(week) \$ 18.00

Estimated cost per (period) \$18.00 (To be filled in by office manager)

The head of the unit which is to do the work, if approved, will report to the office manager at the end of the first week or period during which the new detail was worked, the exact number of hours and minutes that the additional work required, in order that the cost of operation base of the units affected may be adjusted

All new work, before it is commenced, should have the approval of the office manager; before his approval can be secured, the estimated "time required" must be filled in.

Approved John Brown Head of unit requesting work

Approved W. H. M. Fox Office Manager

Exact time required 45 hrs. 30 min. (To be filled in after detail has been worked first time)

Exact cost \$17.40 To be filled in by Office Manager

Date work started 8/1/26

Date base adjusted 8/1/26 Temporary

FIG. 2.—Analysis of proposed new or transferred work.

On line 39 is shown the figure amounting to \$1,182.52 which represents the base adjustments made during the period. Adjustments are made both on a temporary and permanent basis. On line 40 is shown the net reduction without allowing for adjustments, which totals \$544.99.

We are able to balance the figures of each column in Table I with our general accounting records. This gives us a direct proof on the accuracy of the figures.

From: Office Manager

To: Head of Unit 8, Dept. A.

Subject: Current Period Expenses-Cost of Operation
in Home Office

The names of the units, which, during the first _____ periods accumulated, qualified for the HOME OFFICE EXPENSE HONOR ROLL, are listed below in the order of their standing:

- | | |
|--------------------|---------------------|
| 1. Unit 7-Dept. A. | 6. Unit 5-Dept. C. |
| 2. Unit 3-Dept. A. | 7. Unit 9-Dept. A. |

TOTAL \$ 2,128.54 \$ 2,129.36

Economy exercised period \$ 209³⁴
(Red over base-black under base)
Accumulated economy exercised \$ 547⁹⁸

* Compiling Statistics as further explained on attached schedule
* Red figures

OFFICE MANAGER

FIG. 3.—Report to unit heads on cost of operating units.

Control of New Work. The control of new work shown in Fig. 2 has tended to decrease the amount of new work started in the office. The person requesting the new work is now able to measure the need for this work in terms of its estimated cost, and in many cases we have found that the person requesting the new work did not believe the work would cost more than a

fourth of the actual cost. After obtaining the cost figures in a number of cases, the person requesting the work would decide that the results obtained from doing the new work would not warrant the expenditure necessary to work the new detail.

At the end of the year, we have an approved new work sheet covering all of the new work that has been started in the office. You will notice on line 39 a total of \$1,182.52, new work done in the office for the period. At the end of the year, in making the annual report we have available a new work sheet approved by the head of the unit who requested the work, covering all new work.

Progress Reports. The unit heads are kept informed as to their progress in connection with the cost of operating their respective units by means of a report which is given to them covering each period's performance. The form used for this report is Fig. 3. The ten units out of the total of thirty in the office, whose accumulated economy exercised is of the largest per cent to the accumulated base, are placed in the order of their performance on the "home office expense honor roll." The various expenses connected with the cost of operating the units are listed on this form together with the various expenses for the previous period for comparative purposes. The base of the unit is also placed on this form together with any adjustment temporary or permanent which has been made during the period. The economy exercised by the unit for the period is the difference between the total cost of operations and the base as adjusted. If the total cost of operations is greater than the base, the economy exercised is placed in red. The accumulated economy exercised is also placed on this form showing the result for all periods of the operating year to date.

Results. While everything connected with the procedure in accumulating the cost of operation of the various units may not be the very best accounting procedure, at the same time the real test of the plan is whether or not it is getting good results. Our results under the operation of this plan have been very encouraging. We have had a gradual decrease in the cost of operating the office. The economies effected have made it possible for us to return some of the savings to office employees in the form of salary increases. In making salary increases the efficiency of the work of the individual in the respective units is taken into consideration, also the degree to which the individual has contributed to economies effected in the unit.

BUDGETING OFFICE EXPENSE

BY HADAR ORTMAN, *Director of Operations and Finance, Meredith Publishing Company*

Everyone recognizes that manufacturing costs should be very easy to estimate. And, if one further analyzes why he rightfully thinks so, he will find that it is because of the scope of experience that usually has been recorded and the insurance usually provided for obtaining certain results—all due to the existence of control procedures. As a result, manufacturing operations, for many years, have been executed under effective expense budgets. But

expense budgeting, whether it concerns manufacturing or clerical expense without other forms of control, would be of very little value. The expense budget is but a means to an end. It is but the index by which many activities of the operation may be judged and a method of correlating certain other vital information.

There must be available some recorded history of actual performance in order to estimate intelligently future performances. The more detailed these records, and the longer the period they cover, the more accurately the results can be estimated.

There should be some way to check, periodically, actual against budgeted performances. Here, of course, the real value of a budget is brought forth, because through these comparisons the executive is enabled to judge the effectiveness of subordinates' performances and his own, and to prevent future wastes.

It is advisable to provide some additional procedures whereby wastes, beyond budget standards, are prevented.

It is desirable to translate the plans reflected in departmental budgets into long terms and short term plans covering material and equipment purchases, labor requirements, space demands, method requirements, financial demands and other plans for auxiliary activities.

It might be of advantage to provide controls whereby operation executives will know immediately when standards are not reached, without waiting for reports from cost or accounting records.

Let us summarize the uses of various types of control from a budget standpoint.

- A. Provide the basis for budgeting.
- B. Provide means of accomplishing budget goals by:
 1. Providing periodical comparisons.
 2. Providing correlation of plans with other functions.
 3. Providing means of preventing undesirable deviation from budget.
 4. Providing means for immediate corrective action.

Cost accounting, planning, scheduling, wage incentives, job analysis, routines, and other forms of control are all aids to budget or in making budgets effective. However, even though these types of control are, theoretically, always desirable, they are not all essential to effective budgeting and sometimes actually not practical. When such controls are installed, it is usually because of direct benefits which will be obtained; the advantages from the standpoint of budgeting are usually not considered as deciding factors.

There is close correlation between budgets and other types of control. This discussion is limited, however, to the relationship between budgeting and other controls, as providing the basis for and periodical comparisons with budgets. Furthermore, even though all the control procedures more or less serve in this way, this discussion is limited to but two of the controls—accounting and cost accounting.

But before going into a further discussion of budgeting, it is probably advisable to devote a brief discussion to office work from an accounting standpoint.

The office worker is the staff member of the business army. His is the tremendous responsibility of planning the operations, making certain of their accomplishment, checking their efficiency. The entire business rotates around his desk.

Office work is a staff function, or a service function, to the major functions of a business. It comprises writing or interviewing, computing, classifying, and filing. Within these classes there are, as you all know, a great number of different operations.

From the standpoint of executive control, these clerical functions are either made a part of the major functions or separated from them, and, consequently, from an organization standpoint, made into separate service units. In some organizations both types of executive control may be found. In both cases the clerical work may be subdivided as to routines or specialized operations. For instance, an order handling department might comprise all operations connected with the clerical handling of orders. The correspondence division, on the other hand, might control all the clerical operations connected with answering inquiries, except the stenographic or filing work which might be centralized for the whole company or a certain part thereof. In other words, there might be some units serving other units which themselves serve major functions.

In our organization the clerical functions, with a few exceptions, have been separated from the major functions which they serve. We also have centralized certain operations into specialized units. It has proved to be a very successful plan. It is of fundamental importance that accounting, from the standpoint of control, be based on a logical division of responsibility, as this usually can be effectively translated into the accounting method and other types of record control. Even though an organization is rarely built to suit an accounting system, the work of constructing such a system serves effectively as a check on the effectiveness of the organization line-up, and usually opens the executive's eyes to opportunities for changes which will be of advantage.

Accounting and cost accounting, on which budgeting must be built, and through which it is of value as a control, should be shaped entirely to the organization pattern. A separate set of accounts or cost records should be kept for each organization unit, giving the department, division, or section head periodical pictures of the cost items incurred by him in such detail as may be required. As a matter of fact, under certain conditions, it might be advisable, from an accounting standpoint, to segregate the department accounts of one executive into several accounting divisions. This latter applies, for instance, when a considerable amount of clerical work is performed under the direction of the head of the major department. It is often desirable, under these conditions, to establish the clerical work as a separate division on the books.

Furthermore, the relationship between the various service units and the major functions they serve should be accurately reflected in the books of the company. The accounting procedure should provide not only a recorded classification of incurred expenses, but also a fair method of transferring office costs from the office departments to the accounts of the departments

for which work has been done. Very rarely is it advisable to charge office costs directly to the profit and loss statement.

In this way each service department, division, or section represents, from the standpoint of accounting, a business by itself, selling its service to other organization units. Expenses incurred are charged against the division. Credit is given the division for service rendered and charged to the departments for which work has been done.

Credit for work done can be computed in different ways. For instance, a clerical service unit operating for the benefit of one major function only might have a set of accounts on the books, but the total against this unit might be charged, at the end of each month, into the accounts of the major function. Another type of procedure might be in connection with some clerical service unit operating for the benefit of two or more major functions. An arbitrary division of the total cost might be established or it might be concluded that it should be distributed based on the number of orders or the amount of income, or on the number of accounts handled, or on some other similar basis. It might be that each of the major functions will allow a certain amount for work to be done by this clerical unit, which amount is credited to this service unit and charged against the major function concerned. The difference between the allowed amount and actual amount would show whether or not the clerical task was performed at anticipated cost. Sometimes charges are made to other departments, based on number of hours' work for each of these departments, at a predetermined hourly rate. Finally, based on available cost records, a unit price for each type of work handled may be established and used to credit the clerical unit and charge the major functions served. In some cases, you may find it advisable to use two or more of the mentioned methods for crediting a clerical department for work done.

It is quite obvious that the last is the fairest method for distributing service charges to customer departments. It is the method used by us in all clerical units of any importance. However, for some units, due to the multitude of tasks handled and the limited volume of each, we have decided that it would involve too much clerical work to follow this method, and consequently, have resorted to some of the other arbitrary bases mentioned for computing credits. In one research unit where a large group of clerks is employed, the hourly method is used, due to the large number of tasks handled.

From the standpoint of our discussion, we are interested in this question of redistribution of charges only so far as it provides methods of controlling the effectiveness of the clerical work performed and so far as it determines definite aspects of divisions of responsibility for office expense.

In order to obtain a concrete basis for discussing budget, let us consider a specific unit—let us say an order handling department.

Assume that four different types of orders are handled. Type one requires operations *a, b, c, d, e, f*; type two requires operations *a, c, e, f*; type three requires operations *a, d, f, g*; and type four, operations *a, b, e, f, g*. Before making up our budget, let us obtain the figures on the books for the order handling department for the last year. Let us assume that they are as follows:

TABLE I.—ORDER-HANDLING DEPARTMENT

Payroll.....	\$50,000
Rent, light, and heat	2,900
Depreciation, insurance, and taxes.....	4,000
Postage, telephone, and telegraph.....	1,500
Supplies.....	6,000
Repairs and maintenance.....	800
Personnel service.....	2,500
Operation control charge.....	3,100
Sundry expense.....	200
Work done by other divisions.....	5,000
Total.....	\$76,000

Our order handling department head, and perhaps his superior—the office manager—meet with the general manager to discuss budgets. The general manager says, "Our order handling cost for last year was entirely too high, and we certainly cannot spend any more for it next year." And what is the result? The budget amounts decided upon are the same as the actual costs incurred during the last year, without much further discussion.

The year goes by and we are again in the general manager's office. The high official's facial expression promises a hot meeting, as he looks over the result of last year's operations, which shows as follows:

TABLE II.—ORDER-HANDLING DEPARTMENT

	Budget	Actual
Payroll.....	\$50,000	\$54,000
Rent, light, and heat.....	2,900	3,000
Depreciation, insurance and taxes.....	4,000	4,000
Postage, telephone, and telegraph.....	1,500	1,200
Supplies.....	6,000	6,000
Repairs and maintenance.....	800	600
Personnel service.....	2,500	3,000
Operation control charges.....	3,100	3,000
Sundry expense.....	200	200
Work done by other divisions.....	5,000	5,000
	\$76,000	\$80,000
Loss.....		\$ 4,000

Again the manager opens the conversation. "Last year I told you that you had spent too much money on order handling. I finally allowed you the same amount in the budget, but you have spent even more this year. Rightfully, I should fire both of you and the whole department. What good does it do us?" Our clerical executives realize that something must be wrong somewhere; they know that they have worked harder than ever, had better help, had less idle time, and still the "old man" is not satisfied.

They review the figures. It is true that the payroll shows \$4,000 above budget and undoubtedly the largest share of the inefficiency, if any, must be in this item. They notice \$500 more for personnel service for which, of course, they are not responsible. That is the personnel manager's job, and why should they get blamed for him? In this way they discuss each item and decide between themselves that, for at least some of the charges, they are not to blame.

Furthermore, how about the number of orders handled? Did they handle more orders last year than the year before? They have to handle them as they come in, but the number is controlled by the sales manager. They proceed to investigate and perhaps spend weeks worrying and digging for facts, meanwhile allowing the cooling-off period for the general manager. Then, perhaps, they finally succeed in squaring themselves with him. However, they insist that next year's budget should be made up quite differently.

It is quite obvious that the volume of work handled is the basic item to consider when scrutinizing office expense statements. Supplies, for example, include pencils, pens, ink, forms, etc., which must be used in larger quantities as larger numbers of orders are handled. Postage, telephone, and telegraph, covering postage on invoices sent out, telephone calls for local and long distance customers certainly should increase as the number of orders increases. Repairs and maintenance should vary the same way. The more work handled, the more wear and tear is given machinery and equipment.

Charges from other service divisions may include typing of invoices from central stenographic, perhaps computations of invoices from the central calculating division. Certainly, these charges would vary with the volume of orders.

The largest percentage of payroll certainly should be estimated in direct proportion to orders handled. Of course, that does not hold true of supervisors' salaries, which are consistent, independent of volume.

Charges for executive control, including charges for the order handling department's share for the cost accounting, scheduling, etc., usually do not vary considerably from year to year, and certainly should not vary with the number of orders handled. Anyway, the order handling department has no supervision over this work.

Rent, light, heat, and personnel are also fixed amounts, more or less unaffected by number of orders handled, and all under the supervision of executives outside of the order handling department. In reality, they represent book charges made by the accounting department.

It is clear from this discussion that certain expenses are fixed and do not vary with the volume of work handled and at the same time usually do not represent expenses over which the order handling department head has any control. On the other hand, some items vary in direct proportion to volume of work handled, over which items, also, our order handling department head has direct control.

It represents a very definite improvement, from the standpoint of budgeting, to get these figures rearranged so as to show variable costs separated from fixed costs. Table III shows the result as applied to the order handling

statement previously shown. The first section of accounts represents variable, and the second fixed expense. Note that supervisory payroll has been taken out of the regular payroll account and classified among the fixed items.

Grand total.....	\$80,000		\$92,600

If we are to make up a budget for the coming year on the basis of this statement, how should we go about it? First, of course, we want to know the number of orders we are expected to handle during the coming year. Assume that we handled 500,000 last year, and it is anticipated that we shall handle 600,000 next year. Would it be fair to add 20 per cent to the figures shown as incurred expenses for last year? The fixed charges should not

increase 20 per cent. Also 20 per cent added to each one of the variable expenses would mean that the same efficiency would be obtained in the order handling department for handling the anticipated number of orders. Last year the variable costs amounted to \$63,000, and the fixed costs amounted to \$17,000. Consequently, we estimate for the coming year \$75,000 for variable costs and \$17,000 for fixed costs.

Let us now go through the year and get the final statement. It shows \$78,000 variable and \$17,500 fixed.

TABLE V.—ORDER-HANDLING DEPARTMENT

	Budget	Actual	Over + under -
Payroll.....	\$60,000	\$63,000	+\$3,000
Work done by other divisions.....	6,000	5,800	- 200
Postage, telephone, and telegraph.....	1,440	1,300	- 140
Supplies.....	7,200	7,000	- 200
Repairs and maintenance.....	720	700	- 20
Sundry expense.....	240	200	- 40
Total.....	\$75,600	\$78,000	+\$2,400
Fixed payroll.....	\$ 4,000	\$ 4,000	
Operation control charge.....	3,000	3,200	+ 200
Personnel service.....	3,000	3,200	+ 200
Rent, light, heat, and power.....	3,000	3,100	+ 100
Depreciation, insurance, and taxes.....	4,000	4,000	
Total.....	\$17,000	\$17,500	+ 500
Grand total.....	\$92,600	\$95,500	+\$2,900

Can the management say that this apparent additional cost is due to lack of efficiency? Perhaps through an investigation it was found that instead of 600,000 orders, the order handling department actually handled 660,000. Of course, our order handling department head does not control the number of orders handled. Actually then the variable costs should have been approximately \$83,200 instead of \$78,000. Consequently it would mean that the efficiency of the department had been operated above standard instead of below.

Assume that the number of orders handled corresponded to the estimated number. Can the management then fairly accuse the order handling department of lack of efficiency? By no means, because the percentage distribution of types, and consequently the work required, might have been quite different; over these conditions, naturally, the order handling division head has no control.

We have previously pointed out that deviations between budget and actual charges made to the order handling department for personnel work, etc.,

cannot be laid to the order handling department head. This eliminates \$500, for which we cannot hold our department head responsible.

Assume now that the management has in some way convinced the department head that he has lost at least \$2,000 of their good money. What is the department head going to do? He can reasonably assume that the major share of the loss is in the payroll account. The other items are of comparatively small importance. He has seven different operations and fifty clerks under his jurisdiction. There is no way for him to tell if all or one or two of the operations are performed below standard, or if a few or all of his clerks are lagging behind. The only thing he can do is to assume that everything and everybody is wrong, thereby irritating some individuals whose performance might have been very satisfactory, and perhaps should have been praised. An accounting statement does not provide sufficient detail to enable our order handling head to decide on what corrective action, if any, is necessary. An accounting statement, even though revised from its usual form by separating fixed from variable expense is not sufficient then to control intelligently the costs of handling orders.

Assume that we introduce in this scheme a procedure for crediting this department with a certain amount for each order handled. By so doing, we

TABLE VI.—ORDER HANDLING DEPARTMENT

	Budget	Actual	Over + under -
Payroll.....	\$60,000	\$63,000	+\$3,000
Work done by other divisions.....	6,000	5,800	- 200
Postage, telephone, and telegraph.....	1,440	1,300	- 140
Supplies.....	7,200	7,000	- 200
Repairs and maintenance.....	720	700	- 20
Sundry expense.....	240	200	- 40
Total.....	\$75,600	\$78,000	+\$2,400
Fixed payroll.....	\$ 4,000	\$ 4,000	
Operation control charge.....	3,000	3,200	+\$ 200
Personnel service.....	3,000	3,200	+ 200
Rent, light, heat, and power.....	3,000	3,100	+ 100
Depreciation, insurance, and taxes.....	4,000	4,000	
Total.....	\$17,000	\$17,500	+\$ 500
Grand total.....	\$92,600	\$95,500	+\$2,900
Credit.....	\$92,600	\$85,000	
Loss.....		\$10,500	

can readily see that we have eliminated one factor of uncertainty, over which the department head has no control, namely, the number of orders handled. Assume in the previous example that we specify 15.4 cents as the average

costs for handling an order during the coming year. This is based, as you remember, on an estimated cost of \$75,600 variable and \$17,000 fixed expenses for 600,000 orders. At the end of the year we came out with \$78,000 variable and \$17,500 fixed. Assume that the order handling credit shown on the book amounts to \$85,000, or an apparent loss of \$10,500. What conclusions can be drawn? The credit is arrived at by multiplying the number of units handled with the predetermined standard cost. By dividing the credit with this standard cost, we find that we actually only handled about 535,000 orders instead of the anticipated 600,000. This shows that during the year we spent \$10,500 more than the budget for handling 65,000 less orders. Does this mean that our order handling department wasted \$10,500 of the company's money? Not necessarily.

We previously agreed that the head of the order handling department was not responsible for the increased charge of \$500 for personnel work, etc. Furthermore, due to the fact that we handled a volume less than we anticipated, and for which we are not responsible, that portion of the standard costs which was planned to cover fixed costs, was not sufficient. Out of the 15.4 cents allowed per order, 2.8 cents was allowed for fixed costs. Multiply this figure by 535,000. We get \$15,000. The fixed charge amounted to \$17,500. In other words, we have now found \$2,500 over which our department head has no control, and consequently reduced the efficiency loss to \$8,000 for which we may hold our office head responsible. But, again, our order handling department head might defend himself by claiming that the unusual amount of complicated types of orders was responsible for this extra expense, and he might get away with it. Or assume that the management proved its claim that the department had been operated inefficiently, what guidance does our order handling head get from our figures as to where the sore spot is? None. And, we are back to the same picture again, namely, that additional controls are required.

Let us now consider this same order handling department and the same conditions under a plan similar to that which we use for most clerical departments in our company.

Our accounting books are arranged so as to segregate variable from fixed expense, and to allow work done on a standard cost basis. In addition to figures kept in our accounting books we maintain cost and production records covering clerical work very much the same as those found in most manufacturing departments.

Let us go back again to our example for the order handling department with four definite types of orders and seven different operations. In the cost books we will find an analysis of various variable costs by operations, arranged to show volume handled in each operation and, consequently, variable costs per unit handled in each operation. Please note that we do not distribute fixed expenses further on our cost reports as generally, from a managerial control standpoint, they scarcely warrant further work, assuming, of course, that the accounts in the general ledger are as detailed as they should be.

As payroll always is the largest expense item in the clerical department, particular attention should be given so that accurate divisions and fair means of measurements may be obtained on this item.

Other items can be handled in different ways, depending on the amount involved and the work required for making different types of distributions.

Let me suggest a principle which is quite frequently neglected. Assume that in one order handling department we have a payroll of \$20,000 and a supply expense of \$2,000, and in another department of the same kind, a payroll of \$500,000 and a supply expense account of \$50,000. The fact that in both cases the supply expense is only 10 per cent of the payroll does not justify a decision to use an arbitrary method of cost distribution in both cases. In the larger office it might pay to have a number of more elaborate controls of the supply items, because of the total amount at stake. In the smaller office it might be sufficient to total the full amount in one column and divide by the total number of orders handled, independent of types of orders and operations. In the larger office it might be well not only to distribute the supply item to each operation, as consumed, but also to split the amount charged to each operation by types of materials.

In the construction of any cost accounting plan it is obvious that for each item there is a practical limit, determining the extent of distribution and computation which should be made.

As a result of this discussion it can be seen that we sometimes must add several unit costs in order to obtain the cost per unit performed in each operation. Sometimes we have only payroll cost per unit of operation available, while other costs are distributed per unit of final product and independent of operation. But in any case, through our cost records it is possible to obtain the cost for each type of orders handled by adding certain unit operation costs and, perhaps, some unit costs which have been considered the same for each order, independent of type.

In budgeting the order handling expenses under this plan, the logical starting point is with the cost and production records.

TABLE VII.—OPERATION A

	Number units	Number hours	Production per hour	Wage cost per hour	Wage cost per unit
January	50,000	2,500	20.0	\$0.50	\$0.0250
February	60,000	2,856	21.0	0.52	0.0247
March	70,000	3,414	20.5	0.53	0.0258
April	60,000	2,900	20.7	0.52	0.0251
May	50,000	2,222	22.5	0.51	0.0226
June	40,000	2,032	19.5	0.49	0.0251
July	35,000	1,750	20.0	0.50	0.025
August	30,000	1,364	22.0	0.52	0.0236
September	35,000	1,667	21.0	0.52	0.0247
October	40,000	2,000	20.0	0.51	0.0255
November	45,000	2,093	21.5	0.50	0.0232
December	50,000	2,270	22.0	0.53	0.0240
Total	565,000	27,068	20.9	\$0.51	\$0.0245

A careful review should be made of the past experience, as shown by these records, for the purpose of determining fair standards for next year, as expressed in production, per hour and various costs per unit of work to be done in each operation.

TABLE VIII.—OPERATION A

Next year standard.....			22.	0.51	0.023

Whatever improvements or changes are contemplated should be kept in mind in setting these standards. After having reviewed these standards, the various unit cost allowances are added so as to obtain a standard variable cost allowance for each type of order handled.

The next step is to determine the amount of fixed charges. As most of these are distributed charges from other organization units, they are supplied to the order handling department by the accounting department. Fixed payroll is, of course, estimated by the clerical department. In order to simplify this matter we predetermine an amount for each of these charges, which amount is charged, each month during the budget year without change, to each of the departments served.

There are many ways, as you know, to distribute overhead of the type we have called fixed expense. Due to the fact that these charges are the same, independent of volume of work handled, it is necessary to anticipate volume of work to be handled for the purpose of computing the standard fixed cost allowance per unit. Consequently, it is necessary to obtain from the customer departments estimates as to volume to be handled. When these are obtained, the total fixed charges are computed as additions to the variable standard costs per order, based on the payroll item involved, the variable cost involved, or perhaps as an equal amount per order handled.

TABLE IX.—STANDARD COST COMPUTATION

Cost item	Class of orders			
	I	II	III	IV
Operation <i>a</i>	\$0.023	\$0.023	\$0.023	\$0.023

* Based on number of orders..... (600,000)

† Based on payroll..... (60,000)

The standard costs which have thus been computed will be used for crediting the order handling department and charging the customer departments.

One may be surprised to learn that this also completes the budget work, in so far as the order handling department is concerned. What we have done is to budget unit costs rather than totals, by classes of expense or accounts, but without classification. The reason, of course, is obvious.

If we had budgeted the total payroll item, supply item, postage, etc., for the year, a comparison between the budget figures and actual would have shown the sales manager's estimate of volume times the office manager's estimate of unit costs against the actual expenditures for actual volume handled. Such a comparison, as previously pointed out, would not indicate a degree of efficiency.

The standard costs are submitted to the customer departments and are based on their estimates of volume to be handled; based on these standard costs they compute and include in their budget estimate, under the account of "cost of order handling," the expected charges for this work. To them these represent service purchased at a contracted price, and they are responsible for them in the same manner as materials or other services purchased for the use of their departments.

In starting the cost records for the new year, the standard unit costs and the production standards are entered at the top of the respective columns.

Each clerk is keeping a time report showing time spent on each operation. Production records are kept by clerks or supervisors, distribution made of payroll, supplies, etc., so as to conform with the line-up of the cost analysis in our cost records. At the end each month these figures are entered in the cost book.

The actual production per hour and the actual cost of various kinds per unit handled are computed and entered under their respective standard. We now are receiving an automatic comparison between standard unit costs and actual unit costs each month.

The accounting department makes its charges to the various accounts. All the cost distributions in the cost books are balanced against these charges. Credit is given the department for which work has been done on the basis of standard cost for each type of order.

Another refinement has been put into the plan. The variable and fixed costs are shown separately on the accounting department statement, with a subtotal for each and a grand total. In order to obtain comparative figures, a variable credit based on the variable unit costs, a fixed credit based on the fixed unit costs and a total credit, are computed and shown on the statement. We are thus computing a variable credit based on the variable unit cost as well as a total credit.

Thus we obtain an automatic overall check on the efficiency of each department.

Also, based on the elementary unit cost, the cost figure corresponding to each amount and based on the actual volume handled can be computed and shown opposite the actual expenditure on each account, which gives a periodical control as to the effectiveness of each expenditure in comparison with the standard allowed.

Assume now again that we have completed the year, or a month for that matter, and the statement shows variable \$78,000, fixed \$17,500—total \$95,500; variable credits \$70,000, total credits \$85,000—loss \$10,500. From this statement we know that \$8,000 has been lost due to lack of efficiency, and \$2,500 of fixed charges has not been absorbed, due to lack of volume.

When bringing this matter to the attention of the order handling department head, he can, by referring to the accounting statement and the cost

records, tell us on which operation losses have been made, and how much of the loss is due to payroll, supplies, or other expense items. Furthermore, he is able, through a simple computation of time and production records, or through perpetual production summaries kept by individuals, to tell what individuals were responsible for the losses.

It gives our department head a concise guide as to where his efforts are required to bring about a better appearance of his statement. It provides a

definite and logical answer to management inquiries. It gives our department head an opportunity, in a tangible way, to show his effectiveness on his job—an opportunity welcomed by all good executives.

Conclusion. The average accounting record is not sufficient for the purpose of judging the efficiency of a clerical department. Fixed and variable charges should be segregated for the purpose of facilitating budget and control through accounts and to segregate and place responsibility. The most adequate way of providing control through budgets is by supplementing accounting with cost records. These will provide unit cost figures by operations, type of material, etc., enable us to set standards for each elementary cost unit and facilitate effective executive action through the resulting comparisons.

The most accurate way of crediting a service division is on the basis of standard costs, determined on the basis of detailed cost records. Controls of effective value are obtained if, on the accounting statement, the credit corresponding to the variable cost is shown separately. Still better control can be obtained by showing for each major expenditure the amount allowed *versus* the amount actually spent, calculated from actual volume handled and allowed unit costs.

By selling services to other departments, if a standard cost method is used, the responsibility for the volume can be placed with the customer where it belongs. The budgeting of office service units will primarily consist of predetermining operation standards of efficiency.

It might be of interest to insert here an opinion as to the proper procedure for handling over or under absorbed office expenses. During the budget year, they should be accumulated as profits or losses for the individual departments. At the end of the year any departmental profit or loss should be credited or charged to the customer departments, based on the amount of charges made during the year. As a rule standard costs, particularly standard variable costs, should not be changed during the year. The standard fixed cost might be changed if a considerable change in anticipated volume is experienced.

From the discussion above, it might seem that the last described method of budgeting is applicable for all types of clerical departments and operations. From a theoretical standpoint that is so. Wherever there is an office department of any size handling routine operations this procedure is practical and extremely advantageous. However in case of small departments with the multitude of tasks and comparatively few clerks, the combination of accounting and budgeting is sufficient. Of course cost records, individual time reports, material distributions, periodical reports of production from each individual, together with the computation work, require a considerable amount of time. The amount of work involved in a procedure and the advantages to be gained must, of course, be carefully weighed against each other.

In the average sized organization, departments like accounting, personnel, methods, scheduling, cost accounting and others of the administrative or functional staff type do not, as a rule, warrant a cost accounting or standard cost method. Such units, however, as central stenographic, central filing, central calculating, correspondence, order handling, billing, multigraphing, etc. do, in most cases, warrant such a plan. In case a standard cost method cannot

be used advantageously for crediting office departments for work done, the hourly basis is the next best method. For the purpose of distributing administrative and staff functional costs to departments benefiting from their work, any one of several bases might be used—for instance, the amount of payroll, number of people on the payroll, amount of sales, number of orders, or the like.

The importance of shaping budgeting and accounting procedures in accordance with the division of responsibility should be stressed repeatedly. It is extremely important to have the routine for making budget estimates conform exactly with the regular organization channels.

Let us assume that we have an executive organization chain composed of a general manager, department head, division head and section head. If a budget is to be made for a section the estimate should originate with the section head and be approved by the executives above in the order of the organization chart. Any change in a submitted budget which, let us say, the general manager would think advisable, should be discussed with his subordinate executives, down to the section head. A budget to be effective must be based on the mutual understanding of the whys and wherefores. It is just like negotiating with an outside agency and closing a contract when a mutual agreement has been reached in regard to the terms.

A budget computed by a budget director or an accountant is never as effective as it should be and certainly it does not aid in building up the feeling of responsibility, initiative and square-dealing on the part of the executive concerned.

It is important to obtain frequent comparisons between budgets and actual performances in order to accomplish predetermined goals. Reports originating in accounting and cost accounting departments should be submitted at least monthly. We can show on our monthly statements operating figures for the month as well as accumulative for the year.

The March statement shown reveals that our order handling department was operated above standard efficiency since the allowed variable cost is \$100 above the actual. The volume handled was more than budgeted and is shown by the fact that \$62 above actual fixed charges was absorbed. For the first three months the department has been operating below standard, as the variable costs have been running \$1,700 above the allowance. The volume has been practically equal to the budgeted volume, as shown by the figures for the fixed costs. The profit and loss for each type of variable expense is shown separately.

The frequency of the reports, the amount of information on each report and the number of copies to be distributed vary in each case. Remember, however, that possible uses and possible improvements in operations through these records should be weighed carefully against the work of preparing them.

Budgeting of office expense can accomplish several things and in working up the plan the purposes must be clearly kept in mind.

It can be designed to serve as an aid in controlling the financial policy of the company. Also it can be constructed to serve as a measure of work done by individuals and groups of individuals by specifying expectations and by providing a comparison between actual and expectation. It can be made to serve as a coordinator of the plans of the various units of a company and

TABLE XIII.—ORDER HANDLING DEPARTMENT
March

	This month			Accumulative		
	Budget	Actual	Over + under -	Budget	Actual	Over + under -
Payroll	\$5,600	\$5,500	—\$100	\$17,000	\$18,250	+\$1,250
Work done by other divisions.....	500	500	1,400	1,600	+ 200
Postage, telephone, and telegraph....	100	100	250	300	+ 50
Supplies.....	650	600	- 50	1,700	1,800	+ 100

Sundry expense.....	25	25	100	150	+ 50
Total.....	\$6,900	\$6,800	—\$100	\$20,700	\$22,400	+\$1,700
Fixed payroll.....		333		1,000	
Operation control charge.....		267		800	
Personnel service....		267		800	
Rent, light, heat, and power.....		258		775	
Depreciation, insurance, and taxes....		333		1,000	
Total.....	\$1,500	\$1,458	—\$ 62	\$ 4,500	\$ 4,375	—\$ 125
Grand total.....	\$8,400	\$8,258	—\$162	\$25,200	\$26,775	+\$1,575

as a part of the general planning of work that should be done in each organization.

The budget plan should be constructed so as to accomplish as completely as possible all three purposes. It will do so, provided it is properly tied up with other control procedures.

If improperly installed and operated, any type of control is nothing but red tape. In starting a method of budgeting, cost accounting or other control, it is always wise to begin with the items of primary importance, and, when the executives thoroughly know how to manipulate the new "tool," it is time to consider extending its use to items of secondary importance.

It might be said that an expense budget will do in the form of a systematic routine many of the things to which an executive, more or less unsystematically, would have to devote a large share of his time, if he did not have a budget. Consequently, the budget permits the executive to devote more time to improvements, instruction and other types of constructive work which are usually seriously neglected in most organizations, due to lack of time.

In a recent address, Mr. Dwight Morrow said, "It is often assumed that scientific inventions prevent misunderstanding. Machines, however, do not understand each other. Men may make a perfect machine, but it will still depend upon man himself whether the machine will be an instrument of understanding or misunderstanding."

Even though Mr. Morrow talked about machines, I am sure that he also referred to the various systems and procedures that govern action in our materialistic world. His statement certainly does apply to a budget procedure. It mechanizes, that is, it simplifies the executive function but its success as a profit maker and a morale builder depends entirely on the quality of the executive talent behind it.

CHAPTER IX

BRANCH OFFICE MANAGEMENT

BY W. HENRY SMITH, *Assistant Vice President, Retail Credit Company, Inc.*

The Scope of This Paper. This discussion considers the supervisory relationship of the home office to the branch office. By branch office management we refer to the establishment, organization and operation of branches from the home office, where the management group is centered. The paper does not treat the operations within the branch itself, at least not to any degree. The term "management" in the title does not refer to the manager of the branch but to the home office group charged with general planning, supervision and direction of the branch structure. The term "branch" is used to cover a field unit established by and under the direction of the home office. The manager is under supervision from the home office with sufficient authority in his own right to "hire and fire." Factories, warehouses, sales and distributing offices in general would fall under this classification, but the cases cited deal almost altogether with line branch offices which direct selling, credits, collections and office operations in general, as distinct from warehousing and manufacturing.

Basis of the Paper, a Questionnaire. This paper is based upon results secured from a questionnaire which was sent to about one hundred of the members of the American Management Association. Supplementing the answers received, a number of competent division or branch managers of several nationally known institutions were personally interviewed, so that in all, we have forty-nine thoughtful replies to the queries. The quality of the answers is of much more value than the quantity. The information represents a very good spread, most of the concerns furnishing data being recognized as leaders of their particular industrial or commercial groups. This, in itself, means a great deal.

TABLE I.—NATURE OF BUSINESS OF CONCERNS COVERED IN SURVEY

Key Number	Description
1	Insurance (life).
2	Importing, manufacturing, teas and groceries, retailing, direct to consumer.
3	Tanners—manufacturers of leather and rubber belting and specialties.
4	Sale of correspondence courses.
5	Manufacture, sale, and service of an office appliance.
6	Insurance—casualty, mutual.
7	Manufacture and sale of asbestos and magnesia products
8	Manufacture and sale of heating equipment.
9	Manufacturing and selling agricultural implements and tractors

TABLE I.—NATURE OF BUSINESS OF CONCERNS COVERED IN SURVEY.—(Continued)

Key Number	Description
10	Manufacture and sale direct to user—office appliances, folding machines, supplies.
11	Manufacture and sale of paints, varnishes, lacquers, to dealers and industry.
12	Manufacture and sale of advertising specialties of celluloid, metal, leathers.
13	Manufacture and sale of soaps and toilet articles.
14	General banking.
15	Selling company, general rubber goods.
16	Producing and distributing meat and dairy products through the retailer.
17	Reports on individuals—principally to insurance companies.
18	Manufacturing and selling corn products (sales organization).
19	Outdoor advertising—poster panels, paint bulletins, electric signs.
20	Casualty insurance (stock company).
21	Manufacturing suction cleaners.
22	Manufacturing photographic supplies.
23	Manufacturing, selling, and installing elevators and hoists of all kinds.
24	Manufacture and sale of tires and rubber articles.
25	Manufacture and sale of iron and steel sheets, plates and strips.
26	Financing sales of automotive products.
27	Marketing gas, oil, etc.
28	Manufacturing and selling of rubber goods.
29	Street car advertising.
30	Accounts—systems, management engineers.
31	Manufacture and sale of registering devices.
32	Manufacture and sale of cigars.
33	Manufacture and sale of an office appliance.
34	Manufacture and sale of pianos and musical instruments.
35	Manufacture and sale of phonographs and games.
36	Manufacturing, warehousing, and selling of glass.
37	Manufacture and sale of brushes.
38	Manufacture and sale of plate silver.
39	Manufacture and sale of sewing machines.
40	Chain grocery system.
41	Manufacture, distribution, and servicing of automobiles.
42	Manufacture and distribution of plumbing and bath fixtures.
43	Manufacture and sale of heating equipment.
44	Chain department store system.
45	Manufacture, sale and servicing of automobiles.
46	Manufacture and sale of abrasives.
47	Manufacture and distribution of heavy hardware—pipe, plumbing fixtures.
48	Publishers of technical journals—editorial, circulation and printing.
49	Insurance (life).
	Summary
4	Insurance companies.
5	Sale of food products.
4	Fabrics—rubber or leather.
3	Books or printing.
4	Office appliances.
4	Industrial chemical products.
6	Manufacture of machinery implements or metal products.
2	Finance or banking.
2	Special services.
2	Chain store systems.
2	Automobiles.
4	Household utilities.
2	Musical instruments.
3	Miscellaneous:
	Gas and oil.
	Photography.
	Advertising.

Establishment. Why a Branch Organization? In the past few years there has been a definite movement towards parent concerns establishing branches. The Commercial Service Company reported that for the month of August 1929 alone, 52 new chains and 937 branches were established. They may be factories, warehouses, sales headquarters, or complete, almost self-con-

TOTALS: Cos, 49; United States, 4,007*; Canada, 458; Foreign, 461. Average, 82 in United States.

* Not including agencies of companies 39 and 45.

Estimates of employee personnel in branches run almost 100,000.

Figures on home office personnel run over 37,000 with eight companies not reporting home office figures. This high home office figure includes employees in factories.

NOTE.—A few questionnaires were either incomplete or covered less than half a dozen branches and were not used in tabulations.

TABLE III.—MOTIVES FOR ESTABLISHING BRANCHES BY COMPANIES

Answers	Motives	Answers	Motives
44	Service to customer	9	Transportation
16	Accessibility of markets	7	Administrative facility of small units
14	Personal nature of service rendered		Accessibility of raw materials
14	Competition	0	Labor supply

NOTE.—Many companies checked more than one motive. This explains why the total of these figures exceeds 49, which is the number of companies covered in the survey. The figures opposite each item listed indicate the general use or non-use within the group. The same applies to other tables that follow.

1. Hand to mouth buying becoming a national merchandising policy since the war is one prime cause. The retailer refuses to carry heavy stocks. The

manufacturer and distributor must therefore carry ample goods to have them readily available. This means branch factories or branch warehouses and branch offices strategically located. This, however, is not a big factor in the group covered in this paper.

2. Accessibility of markets ranks high as a factor. Management is now under heavy pressure to get the business. Branches are located where the business is or is thought to be.

3. Competition comes in for its share—though this is less a factor than one might first think.

4. Costs have risen. Transportation is a heavy cost factor in many lines. To reduce it one form of branch is established.

5. The chief and most consistent reason, however, in establishing branches is "service to customer" and its related factor, "personal nature of service rendered." This is a far cry in corporate management from the good old trust busting days of twenty years ago. Service—the spirit of progressive American business.

Just what is meant by service to customer? It is not clear from the answers. Undoubtedly though, a service attitude is meant.

TABLE IV.—CHIEF DUTIES OF BRANCH MANAGER

Answers	Duties	Answers	Duties
44	Sales manager	10	Credit manager
18	General office supervision	3	Engineer
15	Service manager	3	Superintendent of plant

Quite frequently the manager combines one or more of these functions. This is nearly always the case whenever specialized departments exist in the office, such as credits, sales, service.

Duties of Manager. There is some correlation between the reason for establishing a branch and the chief duties of the branch manager. Since by far most of the companies reported service to customer as the impelling reason for establishing, so we find most of these branch managers either sales managers or at least having sales organizations in the branch. Customer service and contact go hand in hand with the sales field. Many who reported that the manager was sales manager, also indicate that he is a service manager as well, and that general office supervision is a prime factor of his job. However, the sales manager is often relieved of complicated office structure.

With this setting or background before us we can now more clearly take up a description of the field organization usually found in a branch structure.

The Supervisory Organization for Branches. From Table II it is evident that the average company listed has a high number of branches. A glance at Table V immediately shows that usually there is a supervisory unit between the home office and the line branches. There is generally a territorial division, i.e., branches assigned to a certain territorial headquarters. The

TABLE V.—GROUPING AND NOMENCLATURE

Q. Are several branches grouped under a supervisory zone—district division—territorial unit of some sort? 31—Yes. 15—No.

NOMENCLATURE

Answers	Name of unit	Answers	Title of man in charge
9	District	6	District manager
5	Division	6	Division manager
5	Territory	5	Vice president and assistant vice president
4	Region		
3	Zone		
3	Branch		
2	Departments		Regional manager, department manager, superintendent of agencies, director of agencies, branch managers are found in varying usage
1	Central Agency		
6	Have more than one group between home office and branch—as division, district, branch		

terms "district" and "division" are the favorite names for the intermediate supervisory offices. We find some organizations with many and far flung branches having two intermediate supervisory units between home office and branch. For instance, there may be zone headquarters in charge of vice president or assistant vice president; there may be three to eight zones in the United States and Canada. Each zone has two or more districts under district managers. Each district supervises several branches. Or nomenclature may be regional with vice president or assistant vice president under the regional headquarters, two or more divisions under division managers. Sometimes subdivisions or districts are under the larger divisions. All this is found before we reach the actual line branch office where the product is handled and sold.

In general, the home office prefers to establish territorial headquarters—5 or 10 perhaps—instead of endeavoring to supervise directly 75 or 100 branches. The reason for the trend is obvious. Home office supervisory power tends to break down when branches increase beyond twenty-five. It is too difficult to keep in close touch with what is going on in a branch, or at least, what should go on. The territorial grouping, with proper authority in territorial headquarters, is the logical answer. It is assumed that imposing supervision of this character is justified by more effective results of individual branches—otherwise cost is not justified. Given ten offices to supervise, the division manager ought surely to pay his way handsomely. Just how large a force he needs is a matter of results he gets and the functions he performs. Sometimes he is alone—a free-lance traveling supervisor. Sometimes he concentrates at his headquarters—a battery of staff operations, as training, accounting, credits, and collections—thus often relieving the individual branches which are left comparatively free, small, effective, and stripped for

action. The nature of the business and of the product are among factors in determining the machinery at territorial headquarters.

Probably it can be said that the closer the territorial or branch supervisory head to home office in rank or grading, the more is he a home office man in attitude. The closer he is to the top management group, the better he will reflect the ideas, attitude and policies of the management; the better he will interpret the spirit and desires of the management to the field. In some businesses, the management can afford to be farther from the firing line than in others. Where it is necessary for the outposts pretty thoroughly to reflect the management, it is essential in a large branch organization that one or more intermediate supervisory strata be established to interpret the spirit of the management throughout the field. This delegation of mission is necessary because the personnel of the management cannot directly cover the ground.

Occasionally we find no intermediate supervisory set-up in the field but find one in the home office. For instance, the operating vice president may have three assistants, each fully responsible for a third of the entire territory. Sometimes we find a territorial division in home office, together with a territorial division in the field. One cannot suggest any determining factor here, unless it be the multiplicity of the field units.

Home Office Organization for Direct Supervision of the Field. Tracing on back to the home office itself, there is usually one department or one executive who is the one focal point to which the field organization looks as their direct head. This does not mean that the field is limited in dealing with the home office through this one channel nor that other departments of the home office are required to deal with the field through this one outlet. It is the point of authority, however, through which operation instructions, critical or corrective management, are released, or from which approval must come for staff or functional departments to deal with the field on other than regular routine basis. It is the point to which the field may look in case of a conflict of home office instructions originating in different departments of the business.

TABLE VI

Q. Is there a direct line of supervision from home office to such zone or territorial manager and from latter on down to branch manager? 34—Yes.¹

Line of Authority. Almost without exception, the line of authority runs directly from the home office through the next stratum of supervision on down to the branch. Obviously a division manager must have line authority if he is given supervision of several branches. Authority commensurate with line responsibility is vital.

This line of authority does not, however, require all dealings through the field organization chart channel. The home office often deals directly with branch and vice-versa, but this is on routine operations. In matters of management, promotion, reprimand, the line channels are used—from home office to territorial headquarters—and from there on through sub-headquarters, if any, and from the latter on to the branches.

¹ Those who do not have intermediate supervisory units did not answer.

Operating. With this brief description of the usual machinery or organization used in operating the branches let us now turn to a discussion of just how this setup is employed by the home office or management. This is such a wide field we shall touch upon only a few elements.

These elements are:

1. Releasing important matters to the field.
2. Following up by the home office to see what action the field gets on matters released.
3. Judging the results or performance of the branches.
4. Centralizing or decentralizing office functions and certain clerical work.
5. Setting standards.
6. The degree to which the home office enters in the direction of sales and advertising.

1. *Releasing Important Matters.* Let us presume that most routine matters released from the home office to the field have been flowing through well-oiled grooves or channels; that they have been going out satisfactorily in a routine way. But now assume that a far reaching new idea, or a major change in plans, objectives or policies is voted by the management; how is it gotten out to the field?

TABLE VII.—RELEASING MAJOR MOVES TO FIELD

Q. How are new ideas and major changes in plans or objectives passed on to the branches?

Answers	Methods
39	Letter
28	Personal explanation of traveling representative
28	Instruction sheets
22	Publications
21	Memorandum

Other Methods: Bulletin, conventions, group meetings in field or home office, educational films.

The prevailing ways and means in sequence of their use are: letter, personal explanation of traveling representative, instruction sheets, memorandums. Group meetings and conferences—large, small, frequent, or infrequent—play their part. The conference, however, is frequently not used so much to teach as to set attitudes—get men sold on the main idea. They can get the *law* through instructions at the proper time. The conference is for *tempo*.

Just how general is the practice of organizations in releasing important changes through the same channels and by the same means that a volume of routine is released? Insufficient care in selling the management's ideas is costly, in direct ratio to natural inertia to change viewpoints. Home offices use clever thinking and novel planning to tell the public or the customer about this or that, and too often tell the organization itself in the same old humdrum way. One might even say that a large part of successful management is preliminary preparation for the acceptance of change. It might pay well to have an advertising specialist look over the media we use to tell the field organization.

Are not some things too important to entrust to installation by means of only a letter or memorandum? Do they not require personal or able explana-

tion; a time factor and delay? Yes, some—but a division manager or other traveling representative can cover eight to twelve well separated offices in four to six weeks if necessary.

It is obvious that a combination of these methods is the thing, and the answers indicate their frequent employment in such a fashion.

2. *Following Up.* Releasing matter to the field—whether stimulative or plain orders—is just chapter one of getting the job done. Chapter two is the follow-up.

TABLE VIII.—METHODS OF FOLLOW-UP

Answers	Methods
25	Personal visit of supervisory head, whether field or home office
7	Reports
7	Zone office traveling representative
5	Frequent audits
2	Annual audits
7	Follow-up memorandum or letter
2	Visits to home office
5	No follow-up, leave entirely to manager

NOTE. Also mentioned by individual companies are publications, continuous budgetary control, cooperation.

The various methods seem fully adequate as a group—taken individually, no one may be sufficient. They include reports from branch to home office or from branch to division headquarters and on to home office; great dependence is placed in the monthly report of sales and costs, also audits or surveys by special home office staff men who visit the branches; also by the division manager checking up when he makes his more or less frequent visits. Where the home office supervision of field is tight, the follow-up comes normally through a combination of these methods; where the division or branch manager is pretty much of a czar, the home office seems to release its rules or ideas and expect them to be carried out. In the latter case, how well are they carried out?

One management engineer in charge of a large divisional office with many branches under his supervision says: "Good management of many branches means knowing what they do and when they do it." If his principle is sound, this should provoke some comparison by those organizations who release their messages and thus consider those jobs done. Frequently the release is just the starter's gun for an effective operating department.

Throughout the discussion of operating, it is assumed that the channels of supervision have sufficient authority to get action and get things done when it is known what has been done or not done by a field unit or branch.

3. *Judging Results.*

The leading element in this weighing of the branch is "securing its share of expected business," (profit implied). This, no doubt, means holding old business as well as getting new business, as a high lapse ratio would undoubtedly run up branch operating costs and cut down profits from the branch. Holding old business is a pretty good key to service and performance—so as an index, this factor should rate high. The majority consider ease

of supervision, type and frequency of complaints, and turnover of personnel, factors in judging whether a branch is satisfactory or not—a sizable minority do not attach much stress to these three things—but rely on “holding and getting business and making profit.” Is it not possible that the latter standard used alone may mean some good bets are being passed up? A well-selected and trained personnel, making a smooth-running office and curtailing complaints, is undoubtedly a factor which creates more business and better holds old customers and makes more satisfactory profits. Attention to these things may be a means of raising returns now considered satisfactory into much higher brackets.

TABLE IX

Answers	Factors in Grading Branch
41	Securing its share of expected business
26	Ease of supervision
22	Type of complaints against it by customers
20	Turnover of personnel

Other Things Mentioned: Cost persistency of business; expand business through development of new avenues; development of personnel; contributing to main office information on trade conditions; profits made; inventory turnover and operating cost; capacity to control expense; ability to develop an organization; carrying out policies within and without the branch; number and quality of dealers; effective distribution of product.

4. *Centralization or Decentralization.* The larger the branch territory, the more intensely worked the territory allotted it, naturally the more clerical work devolving upon the branch. Thus we find that most organizations in the survey have decentralized clerical operations and such functions as billing.

TABLE X.—CENTRALIZATION OR DECENTRALIZATION

Q. Have you decentralized most clerical operations and such functions as billing, collections, purchasing, payment of bills, etc.? 29—Yes. 17—No.

Q. Or is the trend to retain all possible clerical work and secondary functions in the home office so as to leave the branch office as free as possible for accomplishing its main objective? 19—Yes. 28—No.

Two reported their organizations decentralized though their trend is to concentrate. This explains variation between the 17 and 19 above.

collecting, payment of minor current bills. One prime necessity for this is that the branch certainly knows local conditions far better than the home office and can make good with its trade or customers on these matters in working adjustments and extensions. Decentralization relieves home office of an enormous detail job which could not be so well handled as by the branch. Two factors that weigh in decentralization of clerical operations are:

a. *Nature of business and kind of product.* For instance, it would be better to decentralize billing and collecting for a small article sold in quantities to many customers in branch territory and especially where follow-up or repeat orders are frequent. Sales of fire engine trucks, on the other hand, would be billed and collected through home office—centralized handling.

b. Size and intensity of sales results of the branch territory. The larger the unit of territory and the higher the volume of individual sales, the more logical the set-up of office operations in branch.

So we find that even in a sales branch organization compromises have to be made, and the sales manager often finds that necessarily his job cannot be limited to sales stimulation but encompasses office and clerical operations which are the unavoidable results of sales.

5. Setting Standards. The setting of standards, both as to methods and as to costs, may be considered a logical function of operating and is therefore included in our discussion at this point.

TABLE XI.—STANDARDS

Answers	Items Standardized
45	Form of organization
44	Office methods
41	Operating instructions
23	Type of personnel
10	Size
8	Volume

NOTE: Type of building, equipment, store fronts, sales talks, training are mentioned as things standardized here and there.

A reference to Table XI will speak for itself as to the consistency with which standardization is practiced in one phase of branch organization or management or another. It is interesting to note that size and volume practically play no part in standardization. Within the individual company, form of branch organization, office methods, operating instructions meet with a high degree of standardization. Type of personnel, though much more of a variable than the definite elements of systems is often standardized so far as possible. My inquiries indicate that this so-called standardization of personnel is not a scientific standardization but rather rough general bases, sales managers are selected from tried and capable salesmen, the typical office managers from those well grounded in the accounting work. Age, education, physique evidently have little influence. Selections are based on general fitness.

The wisdom of standardization of the impersonal things is so apparent, it needs no argument of support. In brief, the practice provides ease of operation, flexibility of operating, ease of opening branches, no jarring of the customer situation or patronage. It also leads to savings on interchange of equipment and personnel.

TABLE XII.—UNIT OF EFFORT

Q. Is a standard unit of effort established for the business handled by the branches, so as to determine the number of people needed by an individual branch? (By 'unit of effort' is meant a measure, such as 1 employee per 10 cars sold; 1 employee per each 300 orders recorded, etc.)

Those using—13. Not using—34. Not reporting—2.

This term is here used to mean a measure of labor, a key to determine the number of people needed for proper organization of each branch. The device

is little used. Either cost accounting or payroll budgeting has not progressed to the point where the unit of effort is recognized as a pay roll control, or else the nature of this or that business does not lend itself to such fine spun cost analysis.

TABLE XIII.—RESEARCH

Q. Is a central research unit maintained in the home office for studying and solving problems of the branches? 38—Yes. 10—No.

Special work mentioned:

Statistics, problems of the trade, customers accounting problems, sales problems, branch operating problems, advertising and campaigns, educational efforts.

Research is such a household word that we need not go far into this. One form or another is generally used for the benefit of the branches.

TABLE XIV.—COST AND PROFIT

Q. Do you set up a certain percentage of profit as a quota for each branch office? 15—Yes. 32—No.

Q. Do you set general standards of cost as guides for individual branch costs? 32—Yes. 14—No.

Q. Is each branch required to operate on a self-supporting basis? 39—Yes. 8—No.

Q. Are the home office costs directly due to any single branch, as shown by the cost reports made for or by the branch, charged to that branch direct? 17—Yes. 25—No.

It is significant that we find few companies applying the principle of the first and fourth questions but second and third are quite generally followed. A deduction would be that branches are allowed considerable latitude in getting their financial results but that they must make a satisfactory profit—though not a standard profit. Perhaps local variations in markets—competition—personnel—make it unwise to compress profits of individual branches into a standard percentage per dollar. If this be true—a satisfactory profit will be above a standard here and below it there.

6. Sales. In the questions on sales which immediately follow, we again face an operating element, as they bring out the operating relationship of home office and branch on sales activity, especially as to direction or control on the part of home office.

TABLE XV.—SALES

Q. If your branch is principally a sales unit, does it carry on its sales activities largely independently of home office direction? 24—Yes. 22—No.

Q. Are sales quotas set by the home office for each branch? 36—Yes. 9—No.

Q. Does the branch office take a part in planning the advertising, or is this centered in the home office and controlled from there?

9 Have branches take part in national advertising plans

8 Branch offices take part in local advertising

32 Centered in home office entirely

The answers to the three questions here show that home office takes quite a hand in directing sales work, even though about half of the branches work independently of the home office. It is the job of the home office, however, to know potential yield of a territory and to set a quota of anticipated sales, and this is almost universally done.

Advertising is closely allied with selling. This is centered in and controlled from the home office. Branches are often consulted for ideas and for application of ideas. For instance, in a newspaper campaign, the branch can often select the proper time and character of advertisement best calculated to appeal to its territory.

Coordination—Elements of the Problem. We have outlined the general structure of the field organization and discussed several elements involved in the operating of that organization. This brings us to a third general division of branch management which we term coordination. Though really a vital part of operating it is given separate treatment because of its importance in any scheme of effective management of branches.

The lone branch seldom has a coordination job in so far as supervising another group is involved. The division or district branch has a coordination problem but a fairly simple one. The district manager is in full authority and can call for such reports as he needs and take quick flexible action to see that his branches are in line. The higher up the scale, the more complex the coordination factor becomes—reaching its apex in the home office itself. The home office must coordinate the work of the entire field on the one hand and coordinate its several line and staff departments on the other, so that they function smoothly and effectively with the field, both as directing and as facilitating units.

TABLE XVI.—COORDINATION

Q. What channels (as shown on your organization chart) do staff departments use to get their ideas to the field?

Answers	Channels
33	Direct dealing with each branch
18	Direct dealing with the zone or territorial headquarters
13	Dealing only through the home office operating department or operations officer

The discussion here is related to that on lines of authority. There would be no logic in burdening the operating department or operating function with having to visé or approve all that is sent from the home office to the field in way of routine. The tabulation shows that staff departments are usually left free to deal with the field without interference by the operating unit. This dealing is assumed to be in the regular agreed scope of staff departments and does not imply that any department can fire away at the field at will and order the branches to do thus and so. This would breed chaos. Circumscribing the lines of coordination are the lines of authority through established channels. The tabulation shows that some concerns use strict military channels in the home office dealing with field, as, home office dealing only with division or district headquarters and not direct with branch. This is not common; for the most part, the home office deals direct with branches

TABLE XVII

Q. Which home office executive makes the final decision when there is a radical difference of opinion between a staff department head and a branch?

Key Number	Home Office Executive
1
2	President
3	General sales manager
4	Vice President or president
5	President, Vice President in charge of sales, Treasurer
6	Vice President, general manager
7	General sales manager
8
9	Vice President in charge of sales or comptroller
10	Vice President in charge of sales
11	President, Vice President, treasurer, secretary
12	General sales manager
13	Division manager
14	General manager
15	Sales manager or general manager
16	Department head
17	Vice President in charge of operating
18	Sales manager
19	President
20	Vice President
21	Director of sales
22
23	Has not been necessary. If so, by Vice President in executive office
24	Comptroller on accounting
25	General manager of sales
26
27	Vice President
28
29
30
31	Sales manager
32	Next man in line up
33	General sales manager
34	Vice President in charge of sales
35	Executive in charge of the major department of the business affected
36	Vice President or officer in charge
37
38	Sales director
39
40	Vice president in charge of stores
41	General sales manager
42	Vice president of sales
43	Vice president of sales
44	Vice president of sales
45
46	Vice president
47	Vice president of sales
48	If deadlocked, executive committee
49	Vice president

A comparison of the company or key numbers of this table with the company numbers of Table I and Table II will show by type of business the home office chief to which the field units are responsible.

on some things and with district offices on others. What is the line of demarcation? I would suggest that the home office operating unit as well as other departments, deal with the individual branch so far as possible on routine and resort to division headquarters when there is a management job—major correction, promotion or intense instruction. Within the home office itself, ought not this same principle to apply—staff and functional units dealing direct with branch or district branch until the staff cannot get results? Then the staff should lay its case before the operating unit which wields the big stick. Would not any other course confuse the field? Can branches operate successfully with more than one master?

Of course in ideal institutions, chartered and recruited in Utopia, sharp differences of opinion and conflict in administration do not arise. But that time is not yet. Since there are occasions when such things must be ruled on and settled, who does it?

This question should have been clarified in the questionnaire, but my interpretation is that the home office executive in general charge of field organization is usually the final arbiter. For instance, a branch manager disagrees with the home office auditing department which figures his standard costs. He and the chief of auditing department can't get together. The manager refers his case to the district manager, who, if he agrees with the branch, sends it on to the vice president in charge of operating—or in the case of a sales organization, to the vice president in charge of sales. The latter takes it up with the head of the accounting department or with the officer who is chief of accounting head and agreement or decision reached; negative to manager, for example. This is relayed to division manager by the operating department and he in turn informs the manager. If it be a point of some consequence, the division manager writes the manager and also lays plans to personally review with the manager at first opportunity. In this instance, branch and home office staff were dealing direct until they locked horns—if branches and staff have horns. The appeal went up through channels. Staff head may have taken initiative and appealed to operating before district manager did. Operating handling should be the same in either case. The situation became one of correcting both division manager and his branch. This is why it had to be thrown out of routine into special line channels. It would not be sound nor safe to permit the involved home office staff department to hand out the correction. That's the posted ground of the operating unit.

So far under this discussion of coordination we have been talking mostly of management relationships. This is simply one vital element in good operating. There are other things—tangible things that come into the picture also. Among these we find the necessity to coordinate purchasing with production, advertising with selling, seasonal expansion with employment pressure periods and in fact all of these factors with each other. The assimilation of changes or new lines require general coordination, involving one or all of these factors and often many more.

The Instruments of Coordination Control. Before leaving this subject, we briefly touch upon the general instruments of coordination control such as:

1. Well-defined and charted lines of authority and responsibility both for the field and for the home office.

2. Committees at home office.
3. Personal contact, home office and field.

The visiting of branches by the home office men is most necessary in the larger points where the rapidity of movement and volume may cause the manager to drift rapidly from practices and policies.

Another plan is to have a home office man in a branch under the functional control of a chief in the home office, but under the direct disciplinary control of a branch manager. The basis for this arrangement to be successful is mutual service to each other. The insurance companies have worked this out very well by having a home office man, usually termed cashier, in the office of the general agency. This type of relationship may be more successful than the plan of having a home office man visit a branch just twice a year to give it the once over. However, such a "cashier plan" may cause friction unless authorities and functions are very clearly set forth.

4. Budgets { Finance, sales.
Time.
Work.

This paper does not present the opportunity to elaborate these items of control technique. It simply points out that budgets should not be restricted to the all too common thought of finance. It is essential in good management to budget other things as well as dollars and sales. Time is a factor that needs to be budgeted. Good coordination absolutely requires that time be given a budget basis. There is a time for work to be done. It must fit in certain schedules to be assured that there is a profit. Throughout budgeting also runs the thought of comparison. Comparison has to be used in framing budgets and in guiding our action by them.

5. Planning.

Planning likewise is too well recognized a factor of management to need elaboration here. Without planning of all phases of the business, there is bound to be some helter skelter operation, some expensive moves. Planning applies to personnel, to product, to sales, to advertising, to all things that concern the management.

One of the keys to coordination is cooperation. A good illustration is that of nationally known manufacturers of automobiles, with thousands of dealers. These dealers are independent agencies. They can close their shops, go out of business, change lines, but here is a vast enterprise dependent upon them. All these dealers take a form of supervision imposed by the manufacturer, use a common accounting system, same rates for service charges and joint advertising. Often you see one ad signed by three or more competing agencies. Why does this thing work? It is coordination through cooperation. Cooperation provides mutual service. To carry the case further, the factory establishes its own supervisory headquarters in each state. This unit gets monthly confidential compilation of sales, costs and profits from each agency, averages all returns for the state and relays the figures on averages to each dealer. Then every dealer can see whether he is above or below average. If his profits are below, he can call on state headquarters to

analyze his books in detail. This service is rendered gladly and points out where his leaks are. Where such conceptions of mutual service and cooperation exist coordination becomes easy. This same lesson can be applied to functions of line and staff, home office and zone headquarters, zone and district headquarters, district and branches. Cooperation and mutual service—that is the principle of coordination.

The Personnel Problem. Now what is the very life of a branch structure? It is the personnel. I had some misgivings about including the questions under the above heading, for fear of duplicating one or more phases of personnel management that have already been surveyed by others. But I could not logically complete a treatment of branch office management without giving a place to one of the most vital elements of such a subject.

TABLE XVIII.—SOURCE SELECTION OF MANAGERS

Answers	Sources
29	Salesmen
8	Assistant managers
	Field
	No special group
12	Miscellaneous
	Foremen
	Office and credits
	Clerks and auditors

a. From what source do managers come?

Generally speaking from the line, from the men on the firing line. Field men are selected for field jobs. Since most of the branches listed are sales branches or have sales units, we find more salesmen being selected than other types.

b. By whom are managers selected?

By the executive in the home office in general charge of branches. This statement should be modified both up and down. The general process seems to be for branch or division managers, who themselves are loyal and well sold on the company, to be charged with keeping on the alert for potential managers. The field, through established channels, recommends or nominates candidates to the chief officer for the field. He usually has some executive committee pass on the selection which he proposes. In only a few instances is the selection reported as left to a field man, but decision is reserved for home office; another case where cooperation is the key to this important job of selection.

Twenty-three concerns report having adopted managerial qualifications. The setting of such qualifications is a management device acting as a balance wheel. It helps to offset pull, pressure, over influence of personality. Qualifications contribute to analysis, wide open weighing of a prospect, rather than blind hunch or the impression of the moment. The questionnaire did not develop any relation between manager specifications and job analysis, but here is a relationship. The higher up the scale we go, the more difficult it is to analyze the job in specific terms and also the more difficult it is to pick managers.

TABLE XIX.—TRAINING MANAGERS

Answers	Place
19	In branch
3	In home office
19	Both in branch and home office

c. Who trains managers?

Branch and home office both take a hand in training. Lacking detail, it can be assumed that in this joint program the branch trains largely in practice on the job—training through doing—while home office gives theoretical as well as actual course of experience in factory and in office departments.

The training is given by branch or division managers—by an officer—or by several home office executives or through organized training departments in the home office. Replies varied so that no generalization is justified. The same is true of the duration of the training period which varies from three weeks to years. If an average could be figured, it would approximate two months at least, or even more. The most significant thing is that a very high proportion of companies trains in one form or another. But there must evidently be a fertile field for central management to develop or improve this training and to plan it expressly for branch office use. This is assumed because of the wide variations in duration of training and in the channels of training.

The foregoing discussion on training calls for a distinction between training and development. The former means learning and becoming proficient in technique; the latter means growth in wider and larger range than mere training provides. The questionnaire did not draw this distinction—but it is nevertheless a very important one and it behooves management to be concerned even more about development of managers and potential managers than about their training. Undoubtedly much development is given, whether definitely recognized or not.

Promotion of Managers. Promotion is universally reported as weighting merit first. Seniority is of little weight, though is often considered as secondary. In general, those who originally selected the manager come in on promotion, except that the branch manager who aided finding and selecting now fades from the picture, since obviously equals are in no position to help much in proposing promotion from their own ranks.

Compensation.

TABLE XX.—COMPENSATION OF BRANCH MANAGERS

Q. Do you have salary standardization in the field? 22—Yes. 22—No.	
Answers	Methods
43	By salary
17	By commission
23	By bonus

A combination of two of the above is found in nearly every case.

Salary is basic compensation for managers.

Bonus and a commission are important supplements; bonus in addition to salary being more common than salary and commission.

This brings us to a kindred table—incentives.

TABLE XXI.—FINANCIAL INCENTIVES

Q. Is there a common program of financial incentives for the higher management group in the field? 36—Yes. 10—No.

Answers	Methods
23	Bonus
13	Sale of company stock below market
3	Profit-sharing

Other forms of incentives are cash prizes, special campaigns, percentage of net earnings of company, group insurance, savings and investment plans, and pensions.

It is accepted as good business to provide financial incentives for branch managers. There is a high preponderance in their favor.

Morale.

TABLE XXII.—CHIEF MEASURES FOR CREATING MORALE

Answers	Measures
44	Promotion from within the ranks
35	House organs
28	Letters or messages from chiefs
27	Training program
22	Suggestion system
17	Published policies
8	Employee representation

Other Measures: Educational aid, special recognition for length of service; employee benefit plans, such as pensions, savings, easy plans for buying stock, sick benefits, social clubs and employee activities, group insurance, and a warm interest of the management in the employee group.

Undoubtedly a prime obligation of management leadership is creation and maintenance of morale. It is a responsibility of management so to organize that employees will have self expression and channels of releasing their constructive thinking. Management that is successful cannot be confined to profit taking and to technical specialization. Satisfactory industrial and personnel relationships are essential to good management.

Summarization. 1. Establishment of Branches. The principle reasons are "service to customer" and "accessibility of markets."

2. Field Supervision and Organization of Branches. The prevailing practice is to group several branches under a territorial unit for supervision and operating purposes. This is especially true where the number of branches is large and geographically extensive. It appears to be a logical and natural step in delegating supervision and direction as the branch office base broadens. It avoids the home office having to spread itself too thin over a large area.

3. Operating. Division and district managers—when reported—and even branch managers when directly supervised from the home office are given considerable latitude in carrying out their jobs. Management depends largely on these managers to carry out anything given them and relies principally upon reports and financial returns as the chief instruments of control. There is a fairly loose system of supervision through personal contact. Guides or standards are set and used in a large measure, but on the whole I

am impressed that the field organization structure created by the management is far ahead of management's technique in using that structure.

More and better planning for the reception of new ideas by the branches; more consistent facilitating service from the home office staff; a closer knowledge by the home office of branch attitude and performance, are suggested as fields for study by management.

4. Coordination. Can be vastly perfected by a wider budgeting of factors other than sales and costs. There is in many an organization a rich field for more frequent constructive personal contacts between the branch managers and the home office heads.

5. In the personnel field of management the suggestion is made that much opportunity exists to develop morale among the rank and file and to better knit the branch personnel structure to the general organization. Development as distinctive from technical training calls for more thought from management in order to keep its manager personnel progressing for heavier responsibilities.

The test of a good organization is the effectiveness with which it accomplishes its objectives. There is no ideal ready made plan that can be fitted to any and every business. It is a fact, however, that there are principles of organization which can be made to apply to the specific problems of any business.

Some organizations work well not because they are inherently sound in organizations or methods, but because of the genius of the management or the unusual personality of one or more key figures in the management group.

Would such organizations then really merit the classification of "good organizations"? Such a description should be qualified. They are good only so long as the present group is in the saddle. After that, what? Perhaps disintegration. It is evident, therefore, a corporate enterprise which expects to progress and live on and on from generation to generation must recognize that its organization and methods should be fundamentally sound. If they are it will continue to function effectively even with one or more of its key spirits gone.

The inference is clear. A sound organization gets results today and is so organized and planned that a corps of men are being developed who will be well able to get as good results or very likely, better results as time goes on.

CHAPTER I

DEVELOPMENT AND ORGANIZATION OF PERSONNEL MANAGEMENT

THE PERSONNEL DEPARTMENT

By J. W. DIETZ, *Superintendent of Industrial Relations, Kearny Works,
Western Electric Company*

What Size and Kind of Business Needs a Personnel Department? A personnel department is a staff group set up to render a specialized service to a company's operating and administrative organizations on all the problems of the business which are grounded primarily in the personnel or human element in the organization.

Such a statement is quite inclusive and perhaps can be made clearer by thinking of business or industry as an interweaving of human elements and material elements (see Fig. 1) with the human element as the warp, while interlocking and interweaving with this element are the material elements—the woof of the fabric.

The warp of the fabric is the human element appearing and reappearing, the strength-giving element holding the entire fabric together and giving it life and character and continuity. In business we speak of this warp as the general forces, management, supervisors, technical experts, customers, suppliers, competitors, stockholders, the public. Andrew Carnegie said that the men were the most important element in his business because with properly selected men he could soon replace destroyed physical equipment necessary to rebuild his business, and J. P. Morgan pointed out that the whole financial structure was built upon character. Our entire experience confirms these viewpoints and so we are justified in making the human element the warp of the fabric.

The material element, the woof, can be defined as raw material, supplies, tools, machinery, buildings, products, territories; and in terms of money it includes wages, salaries, costs, prices, rents, taxes, profits, and dividends.

Expressed in another way we have the following summary of the fundamental elements in business and the functions and activities in relation to them:

A. Elements or fundamentals of business.

1. Human (relating to men). General forces, management forces, customers, suppliers, competitors, stockholders, the family, the public.

specialized and complex human relations problems may be taken care of adequately.

How to Set Up a Personnel Department. Just what specific services and advisory assistance the personnel man or personnel department may render to the administration and operating organizations is problematical; they will vary with the type of business or industrial organization, the nature and number of the personnel, the make-up of the administrative and executive officers, and the personality and ability of the personnel officers themselves. These services will range all the way from the selection of employees to giving personal advice and counsel.

Whether a personnel department should be centralized or decentralized in control and operation is a problem which will have to be settled in the light of all conditions in a particular company. The question naturally arises, To whom should the personnel man report in relation to control or administration problems? Where does he fit into the operating or line organization? Where do the personnel specialists, in relation to training, health, safety, employment, pensions, tie into the organization? Should the personnel man really do any work himself, or just act as guide, counsellor, and friend to everybody else in the organization?

An executive in a large organization once said to me, "I tell my personnel man, 'As soon as you have worked yourself out of a job, you will have rendered the organization ideal service.'" Questioning further, I found that he was trying to emphasize that he wanted his line organization to be headed up by personnel-minded men. In other words, every one responsible for operating activities must be a personnel man, and the problems relating to the human element must receive management attention. It is such a conception that occasioned the comment of Mr. Thayer, formerly chairman of the board of the American Telephone and Telegraph Company: "It is just as important to schedule the development of a general manager as it is to plan a building program." If emphasis is so placed, the solving of material and financial problems, which are controlled by the human element, will take care of themselves. A business executive, ready to place this emphasis on the personnel or human element, is a personnel man. He is a *personnel executive*, this personnel leader, whether he be called president, general manager, sales manager, foreman, or department head. If we look back and review the evolution of organizations now having the reputation of being leaders in sound management practice, we will find that, expressed or unexpressed, this conception of employee relations and this practice have been in effect.

The general manager of a small plant who strives to provide steady work, adequate remuneration, opportunities for advancement, wholesome working environment, and constructive supervision does not need a personnel counsellor to aid him in the establishment of policies or in the organizing, planning or coordination work.

As his business grows, however, and he divides the operating job into distinct functions, such as buying, making, or selling, the heads of these functions may need personnel assistants located at divisional or branch offices or factories. And an employment department, a medical department, a training department, a safety department, a benefit department may be

organized at such locations or at general headquarters to render service in relation to the common needs of all departments. The responsibilities of such personnel assistants as the heads of these departments will differ from those of the line or operating organizations, as these staff people are not responsible for final results; they are responsible only for the quality of their special service and cannot relieve the operating executives or supervisors of their management responsibility for getting results in relation to both the material and human elements of their departmental work.

Each personnel assistant should, therefore, report to the head of the particular organization whose responsibility covers the functional or geo-

FIG. 2.

graphic area served by the personnel assistant and his organization. That is, if the personnel assistant serves a branch sales office, he should report to the operating head of that particular branch, while if the personnel assistant and his organization serve an entire plant or the entire sales territory he should report to the plant manager, or to the general sales manager. For example, in the Kearny Plant of the Manufacturing Department in the Western Electric Company the set-up is as in Fig. 2.

Each operating head is thus responsible for the entire personnel job within his organization. To have it otherwise would be to have divided responsibility in control and operation matters, which we all recognize as unsound

¹ There are four other superintendents reporting to the assistant works manager who have personnel division chiefs reporting directly to them.

business practice. Supervisors must be selected who have not only technical and executive qualifications but who have also leadership and character qualities which will make it possible for them to supervise their people in accordance with the best personnel relations practices. *No matter how equitable, human, and economically sound a company's employee relations policies may be they cannot be realized effectively if each supervisory employee personally does not comply with their spirit in the daily contact with employees.*

In the staff service, such titles as "employment manager" or "personnel manager" are misleading, because in the last analysis, the sales manager manages the personnel in the sales department, and the general superintendent, general foreman, division chief, department chief, or foreman are responsible for every day employee relations in their department. "Manager of employment department," the department which is rendering a hiring and placement service to the line organization, is a much less misleading title. "Manager of training department" is a suitable title within a store or organization which has a centralized staff training service and so, too, a "medical director" should head the medical department and a "safety director" or "safety engineer" should be the title of the individual who renders service in relation to safety work to the line organization.

Obviously, if many such specialists are needed, their work in turn must be coordinated. Such personnel specialists may report through the head of a staff personnel department who of course should report to the head of the organization which his department serves. And as the business grows, as more branches are established, as needs arise for more consistent practices and more careful interpretation of existing policies, a newer type of personnel man may appear—we might call him the "personnel administrator." His duty would be to assist those in control in policy formulation, program planning, coordination, analysis of results. He might be called vice president, assistant to president, general supervisor of employee relations or whatever title will rank him with those rendering similar service in relation to the material elements or the principle operating activities of the business. He should have this status in the organization, not by virtue of "heading up" the personnel function of the business, but because of the recognition of the relative importance of the service he renders to the controllers or administrators of the business. He in turn, if the volume of his work demands, may need to surround himself with a staff of specialists or experts or counsellors who render service through him to the administrative officers of the business or through the operating functional heads to the personnel assistants throughout all the line organization and at all branches and all locations. Such administrative assistants should be competent to promote attention to and advise on such fundamental matters as organization and administration (from personnel viewpoint) joint relationships, financial relationships, employment, vocational adjustment, training and education, health and sanitation, accident prevention, services for employees, and research.

Qualifications of a Personnel Executive. The personnel man is fundamentally a business man. He should be a solver of business problems. So-called personnel experts, narrowly trained in a specific phase of personnel service, thorough and professional as their training may be, will never be able

to render the assistance to operating executives in personnel matters which the business man, broadly trained and experienced in these specialties, will be able to render.

But it is asked, How do we get such personnel executives? Several companies are finding it advantageous to promote personnel men to operating and administrative jobs, and operating men to personnel jobs. Such a rotational program carried out over a period of years should provide each group with a thorough knowledge of all the fundamental problems of the business and provide the broad training of executives necessary for the successful operation and administration of the company business.

Relations of Personnel Men to Supervisors. If the personnel organization in an operating organization has been set up as suggested previously with the personnel specialists reporting to the heads of the line organizations they serve, then the personnel men are on an organization level comparable to the higher supervisors in the organization they serve. They are thus in a position to assist those supervisors in any way possible in the personnel aspects of their jobs but are not in a position to relieve them in any way of the total responsibility they have for the successful coordination and operation of the material and human elements in the entire job.

PERSONNEL RECORDS AND REPORTS, THEIR PURPOSES AND USES

BY ALLEN EVERETT, *Manager, Planning Department, Henry L. Doherty & Company*

The idea immediately suggested by the use of the phrase "personnel records and reports" is a voluminous file of material, never ceasing to pile up, involving no inconsiderable expense for its preparation, and of a somewhat questionable practical value.

What can justify the accumulation of a mass of material such as is being maintained by well organized companies today? It is true that very often the time that had to be taken from the regular work of the employees, for the preparation of some of the records now used, was given grudgingly. And after all why were these records essential when it was only necessary to hire a man and if he proved unsatisfactory, fire him; if he performed well, in the harness, increase his salary and if he continued to do a good job, promote him, and so on? Perhaps organizations did just that—with detrimental effects.

Organizations, and particularly the larger ones, found that this seemingly simple routine was mingled with snarls to which much thought and time had to be devoted for their unraveling.

So management made this work a specialty and centered it in personnel departments or industrial relations departments whose specific job it is:

1. To procure the force of workers.
2. To maintain and improve that force.
3. To carry on this work in complete cooperation with the various department staffs.

Personnel departments soon found that there was a labyrinth of problems which had to be solved and that many questions had to be answered. They also found that the solution of these problems depended upon the discovery of facts and that the facts might be obtained from useful records.

There are any number of personnel problems, which come up for decision, the solution of which could be improved by intelligent study of the facts derived from records. However it cannot be assumed that every personnel problem can be solved easily by the mere preparation of records. The human being is too complicated and too delicately constituted for exact analysis and so pertinent necessary facts are too often not revealed.

For purposes of this discussion the problems confronting the personnel department have been divided into three classifications. They are:

1. Problems involving the individual employee and affecting him personally such as his placement, promotion, salary increase, and his development.

2. General problems of policy affecting the organization as a whole or as a combination of units, as opposed to the individual persons who are to make up those units. This view is from the management standpoint and includes position specifications, salary standardization plans, production standards, and the discovery of unusual ability among the personnel.

3. The problems of imparting to other functions of the organization, information necessary to them in their work including maintenance of proper liaison with the pay roll department, introduction of the prospective employee to the proper department for interview and to the medical agency for examination, submission of expense budget reports to the general manager, etc.

The Application Record. Under the first classification comes the problem of selection of individuals to fill vacancies in the organization. These individuals are brought in for interview by advertising, through employment agencies, through introduction by employees and friends or through the casual visit of individuals seeking employment. Obviously it is of prime importance to secure new employees who will be best adapted to the work. How can the pertinent information be secured and how verified?

The record very generally known as the application blank has been designed to show information upon which decisions whether or not to employ may be based when verified, and supplemented by a personal interview. This information written in this form in the handwriting of the applicant, may be considered segregated into five parts:

1. **Personal information.**

- a. Name, address, date and place of birth, and nationality.
- b. Marital status, dependents, whom to notify in emergencies, and physical handicaps if any.
- c. Basis of introduction to company and memberships in military, social, religious organizations, etc.

2. **Education.**

- a. High school.
- b. College.
- c. Post graduate, with dates left, degrees, subjects specialized in, extracurricular activities, etc.

3. **Business experience.**

- a. Organization employed in at present and names of last few organizations in which employed, including for each, dates of employment.

positions held, salaries received, reasons for leaving, when present connection can be severed and whether or not present employer may be communicated with.

4. References.

a. Names of three or more persons, known in a personal way for several years, and their occupations and addresses.

b. If under twenty-one years of age give parent's occupation, etc.

5. General remarks.

a. Any additional information the applicant desires to offer.

With this information at hand and with the assistance of a personal interview from which to judge the applicant's personal characteristics, the personnel department and the department needing the individual should be able to make a selection. It is important then to verify the information given on the application where possible.

Information given concerning *education* may be easily verified by communicating with the high school, college or institution mentioned, by means of a simple form letter. The form letter would state that the individual was applying for a position and it would ask for the period of time he attended, courses completed, success attained in scholarship and one or two questions on personal characteristics. Replies should be carefully checked with the application record.

Information given concerning *business experiences* may be verified by communicating with the organization previously employing the applicant. A form letter may be used in this case also, and would inquire about the positions held, last salary paid, success attained and reasons for separation. Answers to the question whether or not the company would reemploy the individual should be a practical guide. Answers to these inquiries should be carefully checked with the application record.

Personal references may be checked from answers to inquiries made by form letter to individuals submitted by applicant as references. On the other hand it is so evident that individuals would only give for references, people who would return favorable replies, it is doubtful whether the cost to follow up these references is worth while. But the character of the names given as references very often serves a useful purpose.

When companies are engaged in a business, the nature of which demands bonding the employees, the acceptance of the *bond application* by the bonding company is a strong indication of the trustworthiness and integrity of the applicant. The bond application is made on a form provided by the bonding company and requests information useful to them in their investigation. If the bonding company refuses the bond application, the applicant cannot be employed by virtue of bonding company regulations.

Tests have been designed, and some of them fairly well standardised, to verify whether the applicant can qualify for the work which he claims his experience fits him for. It is not the purpose of this discussion to go into the relative merits of practical and psychological tests. It will suffice to say that various tests for different kinds of work and for personal characteristics have been designed and that relatively few have proved practical to a degree where they can be depended upon thoroughly. On the other hand practical tests in

typing, stenography, adding machine and other machine work, etc., have been found quite useful in that test results compare closely with results of subsequent performance on the job. In this way the ability of the applicant in certain fields of work may be checked before employment.

It is important to know something about the *health and physical condition* of the applicant with a view toward employing only those people who have the best prospects of maintaining satisfactory attendance records. Applicants are therefore given a medical examination by the medical department of the company or by outside agencies.

The results of the examination are tabulated on a medical form and a rating A, B, C, or D, etc., given by the doctor who examines the applicant, based on the content of the report. In this rating for example:

A might mean first-class condition.

B, not first class but satisfactory.

C, D, etc., mean that conditions exist which would make the applicant unfit for employment.

The deficiencies leading to adverse ratings appear in the body of the report. By proper medical care these may be corrected and subsequent examination result in A or B rating, with possibility of employment then. This course is generally recommended to the applicant. The medical examination and report covers eye, ear, nose, throat, heart and lungs, urinalysis, etc. Organizations which have resorted to medical examinations have found that they have been able to eliminate, before employment, a great number of individuals who would ordinarily have been placed at work and whose services would have been lost for considerable periods of time. In many cases the prospective employee did not realize that an extraordinary condition existed with the result that the examination was a benefit to both himself and the company applied to for employment.

All of these forms and reports should be maintained in the personnel department offices and should be available for reference.

The Progress Report. The next general problem is, by what means can the performance of an individual on the job be followed up and how recorded? In order to insure that general information about each individual will be obtained periodically, a report which might be called the progress report may be prepared by the person directly supervising the work of the individual and endorsed by the department head. This report generally includes a *rating scale*, space for certain other pertinent information desired and provision for *general remarks* which may be in order. Rating scales, it seems, are at the present stage of development more subjective than objective. This, and because of differences in the judgment of the raters prevents absolute or precise measurement. On the other hand, intelligent use of a rating scale will be helpful in recording the impressions made by the individual on the supervisory staff.

A convenient form of scale would consist of a list of the items to be checked and a horizontal line after each item. The rater is requested to place a check mark at a point along each line in accordance with the degree of success attained by the individual. It is understood that the extreme ends of

each line denote maximum degree of favorable or unfavorable qualities. The items rated include:

1. Personal impression.
2. Accuracy.
3. Quantity of work performed.
4. Cooperation.
5. Initiative.

In addition the rater is asked whether the individual is overqualified or underqualified for his work or if his interests are absorbed; also what recommendations are made if a change in position seems in order and general remarks. If this report is obtained at least once a year, the management and the individual are assured that each employee's status is considered periodically and not overlooked. The progress report should be supplemented by a personal interview with the individual, by a member of the personnel department, in order to get both sides of the story, and very often there is a story to tell. In this way misunderstandings can often be corrected and also a better gauge of the individual obtained. Results of the personal interview may be jotted on the progress report and filed with the application blank.

The information shown on the progress report will be useful in considering an individual for transfer or promotion, salary adjustment and special training.

In addition to the periodic check-up made at the instigation of the personnel department, the operating department staff will want to keep certain records to show the *history of the individual on the job*. Where the work can be broken down into practical units for measurement, production records can be kept. Comparison of actual results and standards will be an indication of success attained by the individual and be one basis for promotion, training, salary adjustment and removal. These records can best be compiled by the department employing the individual with periodic summaries for the personnel department to file with other service records.

The operating departments should also be interested in keeping *lateness and absence records*, summaries of which can be prepared for the personnel department to file with the service records of employees. Cost of time lost through unauthorized lateness and absence in large organizations is sometimes a large item and one which is susceptible to reduction. Organizations have found that unsatisfactory employee records are not general but are confined to a minority and are often remedied by discipline. Proper coordination with the medical department often results in avoiding extended absence due to illness and the policy of having all employees report to the medical department upon return from an absence supposedly due to illness has been found to reduce unauthorized absence.

The salary adjustment is a problem in which each employee is vitally interested and salary administration is one which is of major importance to the organization. Assuming that the company has standardized on a salary plan, it is important that each individual be given consideration at least once each year. For this purpose a form which might be called the "*salary adjustment review*" can be prepared by the personnel department and sent to the

department employing the individual for consideration. This form would show the name, position, department, salary range for that position together with the present salary and last three or four previous salaries and dates effective. Space is provided for recommendation for amount and date of adjustment. If it is the policy to consider each salary on service anniversary, then the form should indicate that recommendation for salary adjustment is to be given because of anniversary or because of a special reason such as promotion or exceptional performance. The recommendation is then made by the department and passed through regular channels for approval and pay-roll records. One of the major problems of the executive staff is that of training the new employee to do the work expected of him in his position and training present employees to fit themselves better for the work in hand or for more responsible work, or for supervisory positions. Whatever methods of training are adopted some kind of a follow-up for the results of this training should be inaugurated and these results should be written in the progress report and filed with the service record for future reference.

For the accumulation of the history of the individual while on the job, a record which might be known as the *service record* can be employed. For simplicity and availability this blank can very well be printed on the reverse side of the application blank. To it can be posted such information as:

1. Various positions held.
2. Reasons for changes.
3. Salaries received.
4. Educational courses while with company.
5. Tardiness and lateness summaries.
6. Results of tests.

The combined application blank and service record should provide a quantity of information about the status of the individual which will be useful subsequently for considering promotions, salary adjustments, etc. Particularly it will be invaluable as a source of information to the personnel department in locating material within the organization to fill vacancies in the higher up positions. This possibility permits of filling only the vacancies in junior positions with new employees, which has been found good practice.

General Policy Problems. Under the second classification come problems of general policy affecting the organization as a unit, and as a number of component units as opposed to the individual persons who are to fill up those units. Probably the first question presenting itself in this group is: What is the relation between all the jobs of the company and what are the lines of authority and control?

Undoubtedly a clearly defined organization plan showing the organization of each department, and the tie-in with the executive structure clear up to the president will provide the solution to this problem. Reading the plan of organization vertically will show lines of authority and control. Reading it horizontally will show the functional relations between units.

Organizations desire to know what the content of each position is and how much salary it should carry. Stated simply the solution to this problem depends upon a detailed *job analysis* of each position, the classification of all positions in various grades and the assignment of a salary range to each grade.

Organizations that have worked out standardized salary plans along these lines, have found out that it is a laborious and gigantic task but it is apparent that salary administration under a definite plan had great advantages. As a final result, each position has a range of salary. The minimum salary represents what a new employee on the job can be paid. The maximum salary of the range represents the greatest amount the company feels it can afford to pay for that work. Step rates for salary increase through the range, from minimum to maximum can be worked out to meet the average case and to be used as a guide in salary administration. Reclassifications can be made when necessary.

From the results of job analysis, *specifications for each position* can be worked out. These specifications describe briefly the content of each position and are useful to the personnel department as a guide in the employment of individuals to fill vacancies.

Another result of job analysis is the development of *standard practice instructions* which describe with enough necessary detail how to perform the work in each position. These are useful as one basis for the training of new personnel.

Another product of organization plans and position specifications is the setting up of the probable lines of promotion within an organization. A plan of this kind will show the stepping stones to higher positions. It is probable that in the average organization, the responsible members of the personnel department have from experience, a sound working knowledge of all the promotional opportunities so that intricate charts could be dispensed with. However the theory is that an ambitious employee armed with a promotion chart and a full set of position specifications can map out for himself an advancement plan and a course of study which, if successful, would seat him in the president's chair.

Most executives have at one time or another asked the question: What is a good full day's work? Most clerical jobs can be analyzed and their operations broken up into units which may be measured, making due allowance for weighting the various types of units. By adequate experimentation, *standards of production* can be set up against which the work of an individual can be compared. By this method production can be controlled and very definite records kept of performance of the individual. These detailed records should be compiled by the operating department but periodic summaries should be made for the personnel department for the individual service records.

Another problem that management is concerned with is the *turnover* of the personnel. It is appreciated that somewhere between extremes is an ideal turnover figure. If it is too high, the result is extraordinary costs for employment, training, etc. If it is too low, opportunities for the individual are limited. Monthly turnover records by departments and by units of departments will prove useful as a basis for research to find out the reasons for unhealthy turnover.

Results of studies may indicate improper working conditions, inefficient supervision, inadequate compensation in comparison with outside competition and a variety of other causes. The result of intelligent study of the reasons for separations will very often suggest the remedy.

In this same connection it has been found practical for the personnel department to maintain a record of the individuals who have passed through the various significant positions. Some employees will have attained a greater or lesser degree of success than others on the job. A careful study of the service records and personal characteristics of these individuals may give some insight as to the reasons for failure or success which will prove useful in filling future vacancies.

Another problem, in which management is much concerned is the *discovery of unusual cases* of all kinds among the personnel. Some examples of these problems are:

1. Which employees have unusual ability and can be trained for advanced work.
2. Which employees, not performing satisfactorily might be helped by training.
3. Which employees have failed to improve after special training and cannot be considered for promotion or salary adjustment.
4. Which of these employees, not adaptable or satisfactory should be removed.

The *personnel control chart* will assist in locating the more unusual or significant cases. This chart in its simplest form indicates the names, positions, and salaries of all employees, by departments and by units within the departments. It will indicate which employees are at the maximum salary for the position and reference to the service record will show which ones are qualified for promotion when the opportunity occurs and which are not. Other forms of control charts may be prepared in which unusual items of interest will become apparent immediately. For instance a chart showing length of service and salaries on coordinate paper will indicate subnormal, average, and abnormal progress over a period of years. Various other charts may be prepared with a definite purpose in view.

It is questionable whether an involved set of charts of this nature should be prepared as a matter of routine since a considerable amount of time can be consumed in their preparation which might not be commensurate with their value due to changing conditions. The simple form first described, showing the name, position, unit and salary of each individual, by departments should be prepared periodically—say every sixty days—and distributed to the various departments for verification purposes.

Clerical Routine. The third arbitrary classification covers the clerical routine for the liaison between the individual and the organization and indicates some of the forms and records facilitating that routine.

In large organizations where departments are not centrally located, it is convenient to use a small form for the introduction of the applicant to the department having the vacancy, for interview. This saves the time of members of the personnel department. The form, which might be known as the *applicant's introduction* is prepared by the interviewer and shows the name of applicant, position applied for and salary, department, location and name of individual in department for whom to inquire. Provision is made for a space in which the responsible department representative may authorize

acceptance or rejection of applicant. The form then becomes the media for preparation of formal placement tickets.

When an individual is employed, the personnel department must advise certain other departments of the details. For this purpose a four-part check size form which might be known as "*Authorization for Change in Personnel*" can be typed from the "Applicants' Introduction" which shows all details. The first copy is sent to the pay-roll department so that the new employee's name and salary may be placed on the rolls. The second copy forms the current organization file for the personnel department. The third copy is the confirmation for the department where the new employee is to work. The fourth copy is held by the personnel department and used as part of a tickler file for various purposes such as periodic interviews, progress reports, and salary adjustment reviews. The procedure may be followed in the case of promotions, transfers and removals. Convenient forms can be designed to cover miscellaneous items, such as:

1. Order for physical examinations.
2. Order for medical treatment.
3. Order for photograph for service record.
4. Schedule card for vacations indicating employees who must be replaced while on vacation.

It is also necessary for the personnel department to report periodically on volume of work performed by various members of the department for that period including number of:

1. Interviews.
2. Placements.
3. Transfers or promotions.
4. Removals.
5. Salary adjustments effected.
6. Progress reports handled.
7. Periodic personal interviews.
8. Reference letters handled, etc.

Each month, in companies operating under a budget plan, it is necessary for each department to check reports to date and to estimate revisions in expenses during subsequent months of the budget period. A careful survey of expected activities in the personnel department should reveal any differences from the original budget of salaries and other expenses.

*Design of Forms.*¹ No record should be prepared unless it is a well known fact that it will serve a worth-while purpose. As soon as its period of usefulness is over it should be destroyed. Forms and reports should be brief and contain only useful information and therefore, the paper size should be reduced to a minimum with a view toward standard paper sizes. Whether the blank form should be printed, multigraphed, dittoed, etc., depends on whether or not the form represents an internal record or whether it goes to the public and then, where there is a choice, which is the least costly method. The grade of paper should be as light as possible in view of the amount of

¹ For a detailed discussion of this subject see Chap. VII, office management section.

handling the finished product is expected to receive. Wherever volume is a factor consideration should be given to the use of continuous forms and a one-time carbon because a very appreciable savings in time results in the elimination of constant removal of forms from machine, carbon handling and insertion of new form.

PROCEDURE FOR MAKING AN INDUSTRIAL RELATIONS SUBJECT STUDY WITHIN A SINGLE COMPANY

BY GLENN A. BOWERS, *Director of Research, Industrial Relations Counselors, Inc.*

There is nothing mysterious about research technique. Although many crimes are committed in the name of "common sense," this and a bit of specialized knowledge should make it possible for even a person inexperienced in research to carry through a subject study in industrial relations within a single company. Of course, such a one must be able to see things clearly and in an unbiased manner. Experience in labor or personnel administration either in a supervisory or staff position is desirable, but by no means essential. In fact, too much knowledge about or experience with the subject under investigation might serve as a disqualification because of the difficulty which there might be in maintaining a detached position. It is the purpose of this paper to catalogue the steps to be taken in company industrial relations research so that anyone undertaking such a study may be aided in formulating his own procedure.

There are several types of research studies in labor problems. The one here considered relates to the investigation of a single subject in one company by a person in the firm's employ, the purpose being to use the findings in that company. The range of such subjects is wide, a few may be suggested: the rating of employees for promotion; compensation on the basis of employee contribution; paid vacations for wage earners; incentive salaries for supervisors, managers, and others of greater or lesser importance.

In contrast to this type, there is the general survey of industrial relations and the research into a single subject, either of which may be made throughout one company, a whole industry, or a community. While all kinds of research have many points of procedure in common, there are certain peculiarities which differentiate each one and necessarily affect the method of conducting a research study. Objectives may differ as much as may the scope of the investigation.

Strict standardization of research procedure is undesirable and usually impracticable. A free range must be left for the imagination and for the adaptation of the steps to local circumstances. In general, however, the following major processes or operations have to be carried through in making a subject study in and for a company.

Preparation.

1. Selection of subject.
2. Preliminary survey of practice or condition.
3. Determination of objectives.

4. Choice of investigator.
5. Limitation of scope of inquiry.
6. Formulation of procedure.
- Fact finding.
7. Assembly of data.
8. Classification and arrangement of data.
9. Analysis of data.
10. Draft of factual sections.
- Conclusions.
11. Determination of criteria.
12. Draft of conclusions.
- Presentation.
13. Form and arrangement of report.
14. Presentation of final report.

This breakdown of the task into its elements serves to clarify the entire process of research and to simplify the requirements of scientific method. In fact such treatment may be so elementary that it appears to be an attempt "to peep and botanize" over things which are perfectly obvious. However, the frequent failure of industrial researchers to do first things first and the tendency to rush headlong to conclusions make unnecessary any apologies for over-simplification, if such there be.

1. Selection of Subject. Ordinarily a problem to be solved or an outstanding opportunity for improvement determines what is studied by a company; but if a series of reports is planned it is necessary to decide the order of precedence. Such selection depends upon the arbitrary judgment of responsible persons as to the relative importance of each. The main point to be kept in mind in phrasing the title is that it should not anticipate the conclusions. For example, a proper title is *Experience with Attendance Bonus*, while an unsuitable title is *Why the Attendance Bonus Fails*.

2. Preliminary Survey. Before undertaking the investigation proper it is usually desirable to survey the existing literature on the subject and discuss the question with persons familiar with the field. In this way, shortcuts may be found or reports discovered which will make further investigation unnecessary at the time. Also other aspects of the problem may appear which outrank in importance or precedence the subject at first proposed. Thus when a certain company tackled the question of pensions for retired employees, it soon developed that a pension is only one of several items involved in the financial "independence" of the aged worker. The whole field of employee-employer financial relationships was then mapped out for coordinated study to include such things as group insurance, financial investments, savings plans, home ownership, mutual benefit association, and the relation of these to wages and earnings. Furthermore, the brief survey of the pension problem as encountered in other companies brought out the fact that there is as yet no generally accepted solution and that the study needed to be tuned in with the findings of similar investigations in other companies.

3. Determination of Objectives. Unless one knows what he is after there is little possibility of finding it. The objectives of a study are primarily determined by the same influences which caused the selection of the subject. The goal may be merely a quest for better understanding of an

existing condition and its effect upon the workers and the product, such as an analysis of the five-day week compared with the five and one-half-day week. Or the aim may be to devise a new basis for compensation of supervisors and managers, the old flat salary basis having shown itself an inadequate measure of the individual's value to the company. In general the objectives of subject research within a company fall in one or the other of these two types, more frequently in the latter: a mere search for more facts about a situation, or the development of a better basis of operation. It is axiomatic that the objective of a research shall not be the support of an existing belief, policy, or practice, although that may be one of the results.

4. Choice of Investigator. The largest single factor in the character of a study and the resulting report is the person who does the fact finding and prepares the original draft of the report. The selection of the investigator usually determines in advance the nature of the conclusions. A hard-boiled superintendent may turn out to be a "bull in a china shop" if assigned to analyze the field of employee publications, while a sensitive "welfare" worker might be "innocence abroad" in a study of contractual relations between employer and employee. The experience of the investigator ought to be such as would aid him in discovering the widest range of facts and perceiving them in their true light. Needless to say he should have imagination and a capacity to detach himself and his views from the case in hand.

The investigator may be chosen when the subject is selected in which case he will aid in the preceding steps.

5. Limitation of Scope of Inquiry. The scope of an inquiry may be limited first as to subject matter and second, as to sources of facts. In the latter case the study may be confined strictly to one department, to one plant, or to any other group, or it may extend over the entire company. Regardless of such limitations, certain pertinent information may be found outside the company, in addition to that obtained in the preliminary survey, such as public or confidential reports on the same subject in other industrial units. These outside data furnish a background for the internal situation and rarely can a local problem be analyzed adequately without some consideration for the experience of others with a similar problem.

6. Formulation of Procedure. Although the formulation of procedure naturally is one of the first steps taken, it must be preceded by the five processes discussed above. The plan of work covers not only the schedule of steps but as well the specific sources of data and the methods to be used in exploiting them fully. Where are the facts to be found? Who is best informed on the subject? Are there written records to be searched? Will a questionnaire need to be filled out or will the information be obtained through personal interview? How much time is allowed for the study? Will there be traveling during the fact finding? These and other questions of this character need to be answered in the course of outlining procedure.

7. Assembly of Data. Having completed the preparation, the actual assembly of data may proceed. This presupposes a detailed preliminary classification of the kind of data desired, although it may later be discovered that no tangible evidence exists on all of the points included in the outline. If the information is in statistical form care needs to be taken that the original

records are used or that available analyses based on them are technically sound. Such data must of course be comparable and capable of exact definition. For example, in the case of labor turnover, the formula for calculation of the rate of turnover may be unfit for use in a particular instance in that it paints an erroneous picture, whereas a study of stability of employment showing the length of service of employees might throw an entirely different light on the subject.

The data assembled should be inclusive or the selected sample tested to insure its representative character. A study of wage rates may have little significance in a seasonal operation as compared with a study of earnings.

Data are elusive if unrecorded, therefore, the necessity for copious notes—notes which are far more complete than will ever be used. Interviews particularly should be summarized if later to be used as a basis for judgment.

Fact gathering involves fact selection but the wise investigator will take every pertinent item he can get his hands on even though only a small portion may eventually be incorporated in the report.

In the process of fact finding, certain questions need to be asked which test the hypotheses formed for the particular study. Are the data being gathered reliable and accurate? Can they be verified? Are they relevant to the case being analyzed? Concepts must be formed on these points subject to correction or proof in the course of the investigation. Such an hypothesis in the case of a study of an employees' investment plan might be: Labor turnover is lower among employee investors than among those who do not own stock in their employing company.

This may or may not be a correct assumption, but it is capable of factual analysis in the course of the research.

8. Classification of Data. Frequently it is difficult to classify data accurately during the gathering of it. Information on certain phases may be found in several places and at different times. Filing, corresponding roughly to the preliminary classification, may be resorted to pending later sifting and arrangement in preparing the factual sections of the report.

9. Analysis of Data. The classification and arrangement of data are mainly mechanical processes. Although good judgment is required, these operations are frequently clerical in nature. On the other hand, an analysis of the facts demands an insight which will bring out their true significance and interpret them fully. This process should not be confused with that of drawing conclusions. It is rather a part of the description and identification of the situation as it is found to exist. A careful consideration of data which at first glance appeared pertinent may result in discarding it. Thus the average length of service of all employees may be an interesting fact and yet be thrown out because it varies so much between groups that the figure for the entire company not only fails to have significance but may actually be misleading.

10. Draft of Factual Sections. A final process in the development of facts is the textual presentation of them; a stage at which misinterpretation may creep in. Even with the exercise of great care and without intention, the investigator may misrepresent what someone has told him or he may have failed to observe all of the significant features in the data. Hence the practical necessity of checking back with his informants as to the content, form,

and phraseology of the descriptive sections prepared by him. In case a proposed correction involves merely the manner of statement without distorting the facts, it is usually good policy to accept it. If there appears an effort by an interested party to alter what the investigator feels is the correct picture, the latter must rely upon his own judgment or include the proposed change with his own comments thereon. Rarely should it be necessary thus to present conflicting descriptions of fact. This process of verification of the situation as presented and described is a stamp of approval in the form of an agreed statement of facts on which future consideration of conclusions may be based.

The completion of the descriptive section, however brief or extended, before undertaking to formulate conclusions has the important virtue of separating facts from opinion. If carefully pursued, it removes from the fact sections all indication of conclusions which inevitably take shape in the mind of the investigator in the course of his research. This separation of fact from opinion has the added advantage of clarity for those who later read the finished report.

11. Determination of Criteria. In everyday affairs decisions must be made promptly and without much ado. Some folks have developed an unwritten code or set of principles which serves as a measuring stick for any set of facts presented to them. Unfortunately, however, not every person is so constituted that his standards, hastily recalled to mind, furnish a reliable basis for judgment. Here we are talking about research which inherently requires time and deliberation. The setting up of criteria for the appraisal of facts obtained through research is one of the requisites of the "scientific method." Thus even in a relatively narrow inquiry, it is well to give specific thought to the basis for judgment as well as to the facts brought out in the study. Needless to say, the quality of the conclusions drawn depends upon the reliability of the criteria used.

What are the aims in the practice being analyzed or the plan being devised? Are these aims economically and socially justifiable? What quantitative or statistical records exist to indicate the accomplishment which might be expected under favorable circumstances? What has been the experience, including historical developments? What has been the experience, including historical developments, with subjects closely allied with or similar in character to the one being investigated? What is the prevailing judgment of experienced persons as regards principles underlying the subject at hand? Answers to these questions however unsupported by positive knowledge will ordinarily provide a yardstick for appraising the set of facts in hand. Such questions pertain to basic assumptions which constitute the background for the study. Opinions may differ as to any set of standards which are selected. Without pleading for their soundness the following are illustrative of general criteria for appraising a plan for an employee's investment in stock of his own company:

Thrift should be encouraged, for a thrifty employee is more desirable than one who does not save.

Financial stability in wage earners' investment is more important than possible high rewards with speculative risk.

An employee who has money invested in his employing company tends to give more conscientious effort than one who has not such a stake.

Some of these criteria are capable of proof or disproof but regardless of their validity they represent the kind of a measuring stick which often has to be used to test out the provisions of a proposed plan.

This emphasis on setting up of criteria may seem to be overdrawn, but it is a process which everyone uses when he formulates conclusions. A danger lies in the failure to isolate and recognize the criteria in each specific case. The setting up of indisputable criteria can scarcely ever be accomplished. In fact, almost any criterion may be made the subject of a separate investigation.

12. Draft of Conclusions. In drawing conclusions in the illustration just used, certain questions in connecting the facts of the case with the standards naturally arise: Does the plan encourage thrift? Does it give security of investment? Are the terms such as are likely to be accepted by employees? If the original assumptions or criteria are sound and if these and other questions are answered affirmatively then the conclusion naturally is that the proposed plan should be adopted.

In formulating conclusions the widest possible use should be made by the investigator of other persons' judgment based on the facts on hand. Pride in authorship and proprietorship of ideas may have a place in some research fields, but when displayed in the type of studies here discussed, it usually represents a short-sighted viewpoint. Through clearance of conclusions in draft form with persons authorizing the report whenever possible prior to the final report, opportunity is offered for improvement in statement without necessarily changing the intended meaning. In case of conflict of judgment the differences of opinion ought to be set forth in the report.

13. Form and Arrangement of Report. The general appearance of a report, including the orderly arrangement of contents often has considerable influence on the reception it gets. A piece of work involving several hundred dollars or more in salary and other costs deserves a decent cover and typography. For the convenience of the busy executive, a summary of findings at the front of the report may make unnecessary the careful reading of all supporting evidence. Nothing will win approval for the researcher more readily than the placement of the proverbial "crystal ball" where it can be easily found.

14. Presentation of Final Report. Finally the completed report is presented by the investigator to the one who assigned the task, preferably in person.

Experienced executives may ask, Why all this fuss about unimportant details? In the first place, business people are relying more and more on facts and less upon hair-trigger decisions. Furthermore, there are certain basic principles of research which are likely to be overlooked unless care is taken. The following are a few of the fundamental requirements in sound research method:

1. Plan carefully but not rigidly.
2. Get all accessible facts.

3. Take copious notes.
4. Classify data.
5. Strive not to fix opinions while assembling data.
6. In writing, keep facts separated from opinions.
7. Formulate conclusions only after fact finding is completed.
8. Present report accompanied by brief summary in form for easy digest by its readers.
9. Throughout maintain an impersonal, unbiased and broad-minded attitude.

As we look back over this apparently devious path obstructed occasionally by high-sounding words such as hypotheses and criteria, it is observed that every step is a simple one. When once the habit of straight thinking has been acquired, as when a child learns how to walk, there isn't much mystery left in the process. Without this habit of using good common "horse sense" the industrial researcher is likely "to waddle" along in his thinking awkwardly as one who has never learned the art of walking.

TRENDS IN PERSONNEL ADMINISTRATION¹

By W. J. DONALD, *Managing Director, American Management Association*,
and E. K. DONALD, *Editor, American Management Association*

There are so many different industrial sections of the United States of America, each of them influenced more or less by the dominance of different types of industry and affected by different stages of industrial development, that any attempt dogmatically to indicate the personnel trends in America is likely to be subject to so many lines of dispute as to make the effort almost reckless.

This paper will, therefore, attempt simply to survey the most outstanding new developments and to indicate trends which are likely to become most marked in the next few years.

Organization of Personnel Administration. The time was when personnel work was largely regarded as the job of the personnel man and there were many persons who argued that the personnel department should have entire control of personnel administration. This was true particularly of the period from approximately 1914 to 1920, when personnel administration was being rapidly developed and when personnel men were struggling for a degree of recognition, influence, and even authority which previously they had not had. The natural result was that with notable exceptions there was an overemphasis of the authority of the personnel man and an underemphasis of the personnel functions of the line organization from foreman to president. This resulted in many conflicts of jurisdiction and authority which were very disturbing to the effective execution of a personnel program.

Since the great depression in 1920 and 1921, including among many other things some deflation of the personnel movement, a rather different point of view has grown up.

¹ Reprinted by permission from *Harvard Business Review*, January, 1929.

In the first place, it has become a generally accepted principle that personnel administration is a function of every person who supervises others in the organization. One hears speakers and finds writers discussing the qualities of foremen in terms of whether or not the foreman is a good personnel man, and there are even references to presidents and general managers as good personnel men. There are not a few presidents of companies who openly make the statement that they are the chief personnel directors of their companies.

As a result, personnel men, instead of claiming that they have absolute power in selection, placement, and dismissal of workers, regardless of any preference or conviction on the part of the foreman, are now claiming that it is the function of the personnel department to facilitate the work of the supervisor in dealing with the personnel problems involved in management. "Facilitation," the admirably expressive term used by Oliver Sheldon in his excellent book, "The Philosophy of Management," is a term which is beginning to make its influence felt in the United States and a term which gradually is being used more and more generally. The personnel department is thus being recognized as a facilitating department, its functions being to assist the organization in the preparation and execution of personnel policy through research, advice, and cooperation.

Organization for Selection. An employment manager, for instance, does the initial job of weeding out the applicants for employment, selecting those who would have a fair chance of fitting well into the organization, and referring them to the supervisor who is in need of additional help. In making this selection, the employment manager, of course, weeds out persons whom the supervisor might be disposed to employ but who would not fit well into the organization. It is still true, and probably will continue to be true in the majority of companies, that no supervisor will be permitted to employ men who have not had the approval of the employment department. But the power of employment managers to prevent a foreman from dismissing an employee from his department has practically disappeared. Every foreman has, or should have, the power to dismiss from his department, referring the employee to the employment department either for a final separation from the company or for transfer to some other department. On the other hand, most personnel departments have the responsibility of transferring men from one department to another within the company even against the wishes of department heads who may wish to keep men in their respective departments. In common practice department heads have learned the value of cooperation in this matter, and transfers are made without friction.

In the light of this newer point of view, responsibility for results is clearly indicated and there is no confusion as to authority in regard to the administration of any department of a company. In cases where supervisors have an unusual turnover or seem unwilling to cooperate with the employment department, either by releasing men for transfer or by accepting a reasonable proportion of men selected by the employment department for employment, the solution of such difficulties lies in the possibility of the employment department's recommending to executives, higher up than the offending supervisor, the possibility of the removal of the foreman or the correction of the abuses for which he has been responsible.

Training of Supervisors. In the development of the principle that personnel administration is an integral part of management, there have been several other evidences of progress. For instance, it is customary for supervisors to participate in the preparation of such documents as a manual of employment procedure or a syllabus of instructional outlines for the training of employees. Members of the line organization, including the foreman, are much more likely to cooperate in carrying out the personnel program when they have had a part in the preparation of the policy and program and of the tools which are to be used in making them effective.

One very logical corollary of the newer point of view is an effort to train the supervisor in the process of carrying out the company's personnel program. In some companies this has been done informally for years and is simply instinctive good management. Indeed, there often is no thought-out philosophy with regard to such an interpretation of policy. It is merely an expression of the good sense or natural inclination of the leaders of the business. But in very large organizations, even though the upper executives have this spirit and vision, it becomes extremely diluted before reaching the lowest ranks of supervisors. Therefore, it is highly desirable that some more or less formal steps should be taken to convey this policy effectively down throughout the organization.

In the last two or three years a few companies have begun to train the supervisor in the carrying out of the company's personnel program. Without such steps, the personnel work of a large organization is likely to fall down at its weakest point, and all the energetic, intelligent and well-informed efforts of the director of personnel will scarcely get past first base unless steps are taken to strengthen all the positions on the team by which the personnel program of the company must be carried out.

Organization for Training Employees. This need for training all along the line finds expression most clearly in a company's program for the training of employees. The training of rank-and-file employees has been conspicuous in American industry for nearly thirty years. At first the emphasis was primarily on what might be called education as distinguished from training. In a good many cases such an educational movement was initiated by an executive officer of the company who himself had had comparatively few educational advantages and who was inspired to give to his employees advantages which he had not enjoyed himself. The motive was essentially philanthropic rather than economic, and the driving power was emotional rather than intellectual. A contributing factor was the need for training in English and citizenship for the large number of non-English-speaking immigrant workers. A good deal of the instructional material had little bearing on training for the job and might be regarded as a substitute for the work of the public schools.

During the war and its attendant industrial boom, industry was forced to lay emphasis on training for the immediate job, the consequence being a rapid growth of vestibule schools which provided quick instruction in the elements of performing the job. Consequently, there was a shift from an emphasis on what may be fairly called industrial education to job training.

Meanwhile, industrial training began to feel the influence of different pedagogical ideas. Whereas the earlier instruction offered by companies was con-

ducted by what was called "corporation schools" with formal class rooms, instructors, etc., the newer tendency was for training the worker in actual production under an instructor foreman, and this change in method brought such quick and effective results that it was a very large factor in making possible the increase in wage levels which took place during the long boom period from 1914 to 1920.

The Project Method of Teaching. Into American business has come of recent years a group of advanced pedagogical thinkers from the university schools of education. They have brought with them the project method of teaching, involving what we now commonly call training on the job, and the preliminary steps that were taken during the war have in some quarters been carried much further to the extent that the supervisor, regarded as the real teacher of the worker, is being trained in the process of teaching so that he may perform his functions better than ever before, better than the training function was performed by corporation schools and better than it was performed by the foreman or the journeyman before the era of corporation schools began.

The president of one of our most progressive companies has frankly said that management is in large measure an education and training job. He illustrates this by telling how on one occasion a number of executives of his company analyzed management in terms of specific operations and that after classifying all the typical operations, nine out of ten of them were listed under education and training. The reasonable inference from this analysis is that a great proportion of the training falls upon the shoulders of the supervisor and, in order to get that training done effectively, he himself must be taught to train. This naturally raises the question as to *what is the function of an educational or training department*. The answer may be given under four main headings.

1. To provide that enthusiasm and promotive quality which spreads interest in training throughout the organization and creates desire and willingness on the part of every supervisor to take part in the training process.

2. To help to prepare the instructional outlines to be used by supervisors in the training of their workers. One says help advisedly because it may easily be recognized that when the supervisors themselves have prepared the instructional outlines with the help of an educational department, they are much more likely to take an interest in the training program and to feel a definite responsibility for making it actually effective.

¹ One of the largest electric manufacturing companies has practically done away with all formal classroom instruction of employees and is concentrating its efforts on training the foremen to train others. A syllabus for supervisors in an electrical public-utility company consists almost wholly of material which deals with teacher training for foremen. The assumption is that in order to make the training program really effective, steps must be taken to have the training of the worker continuous from the time of entering the plant until he leaves it, and the principle is followed that the best training is that which is given in connection with actual work under normal circumstances of supervision, incentive, and responsibility.

3. To prepare, improve, and constantly revise the procedure for carrying out the training program, thus facilitating the work of the supervisor.

4. To take a very active part in training the supervisor to train.

On this point it might be argued that the higher executives ought to have the responsibility of training the supervisor to train, and doubtless as time goes on they will participate more generally in this phase of the training program. There are instances where a general manager has actually taken this position, and, having done so, has expected his associates next in line to take the same attitude with those further down in the organization.

Research in Personnel Field. Reference has been made to the advisory relationship of a personnel department to the line organization. It will be recognized, of course, that the effects of sound advice must be based not only on the personality and promotive qualities of the director of personnel activities, but also on scientific research in the field of personnel management. Incident to this changing conception by reason of which the personnel job has been placed squarely on the shoulders of the supervisor, the personnel department has been relieved to a considerable extent of what may be called operating personnel responsibilities, and is thus left time for more intensive research into the personnel problems of the company. Consequently, personnel departments are less disturbed than formerly by interruptions and are better able to concentrate on more fundamental investigations of personnel problems. These have taken many directions, such as research on hours of work, bonus plans, pensions, profit-sharing systems, group insurance, suggestion systems, employee investments in company securities, savings plans, mutual-benefit plans, discovery of methods of labor stabilization, and have even led to the developing of wholly new lines of products intended to fill in seasonal gaps in employment.

Sales and Office Personnel Problems. The end of the war marked the beginning of more severe competition due in part to excessive plant capacity. But the competitive struggle became intensified through increasing competition between lines of industry producing substitute commodities; the radio has begun to take the place of the talking machine, cement is making inroads in the construction industry, giving brick and steel construction a new line of competition more severe than they ever experienced from within their own industry. Improved transportation facilities bring sources of supply in competition with each other which formerly were serving non-competing territories.

The result has been a severe demand upon the manufacturing end of business to bring costs of production down to even lower levels. The factory executives have begun to protest and to urge that similar economies and reductions of unit costs be made in the marketing and administration expenses. As a consequence, personnel problems, which at one time seemed to be confined largely to the manufacturing side of business concerns, now are beginning to be recognized more and more clearly in the distributing and administrative departments. Office-personnel departments and sales-personnel departments have been established in many American companies during the last few years. Banks and insurance companies are giving attention to office personnel problems in much the same manner that was formerly given to manual workers by manufacturing companies. The careful selection and

training of salesmen has become recognized as important as the training and selection of labor.

Organization of Personnel Departments. Another result has been that not infrequently a company may have several personnel departments existing side by side. An office manager who is also a manager of the office-personnel department, a factory-personnel department, and a sales-personnel department may be found in the same concern. In a company with several plants there are usually managers of personnel departments at each of the factories, with a central personnel department which has no authority over the personnel men in the various factories or other units, but which cooperates by providing information and advice for the personnel men in the various units as well as for the major executives of those units. There are instances of marketing organizations which have managers of personnel departments in their branch offices.

Some years ago it was not unusual for companies to have several men each in charge of a phase of the personnel work. A company might possess an employment manager, a manager of the educational department, a secretary of the pension committee, a secretary of the mutual-benefit association, a safety engineer, etc. In recent years there has been a tendency to coordinate these activities into one personnel department in charge of a chief assisted by specialists in the various problems of personnel.

One typical personnel department is headed by a supervisor of industrial relations who has as his associates a safety engineer, a manager of the employment department for headquarters, a personnel statistician, an educational director, a manager of the company store, and a medical director. Most of these have an advisory relation to the executives of branch offices and branch factories as well as to personnel men in those respective units.

The position of the personnel man in the general organization differs in various firms as is often indicated by his title. There are a number of instances of personnel men who are staff vice presidents of their companies. "Employment manager" was a title very generally found a few years ago, but at present it has been superseded in many concerns by titles containing the word "personnel." For a time the title "personnel manager" was spreading rapidly, but recently such titles as "director of personnel activities" and "supervisor of industrial relations" have become more common. The fact that the title personnel manager is gradually disappearing reflects the point of view that the personnel man does not manage or direct the personnel, but rather manages or directs the work of the personnel department. The management of the personnel has become increasingly the province of the line supervisor. There is, however, very little uniformity in titles: "Manager of personnel activities," "service manager," "manager of training activities," and many others are found at present in common use.

Certain definite trends may be recognized in the various phases of the activities of personnel management.

Wages and Salaries. There has been a very marked tendency toward the growth of extra incentives in the compensation of employees. There are, as is well known, a great variety of formulae for setting up a compensation plan, about twenty-five of them being known by the names of the men who

invented them. There are, in addition, a great many others which are adaptations of these.

One of the most significant developments is a comparatively rapid growth of group bonus plans for manual workers, intended to give additional compensation to the group on the basis of the output of the group. Sometimes these groups consist of men engaged in work of the same kind but in which several men must cooperate. In other cases, the group consists of men who carry on a series of operations through their several steps. In some cases the foreman is included in the group or at least receives extra compensation based on the output of the group.

One of the distinct advantages of the group bonus plan is that it puts a premium on cooperation, encourages workers to insist upon their fellow workers doing a fair share of the work, and being on the job promptly each day. In some cases, it encourages the worker to help train his fellow worker.

In dealing with the sales force extra incentives through commission plans or bonus plans are becoming very general. Until recently, however, there have been comparatively few instances of compensating office employees on the basis of a measured output. This has been due, in large measure, to the difficulty in measuring the output of various classes of office employees. In the last few years, however, some very substantial work has been done in developing methods of measuring office-employee output. The number of companies which are applying these methods is rapidly increasing, and new techniques have been evolved for measuring certain classes of office work which previously had defied measurement.

This development is making it possible to compensate office employees on the basis of their output, and the next few years will probably see a very substantial development in this direction.

An intermediate stage in the compensation of office workers has been the development of what is usually referred to as job classification and salary standardization, in which jobs are rated and classified and minimum and maximum limits set for classes of jobs.

Profit Sharing. In general, it may be said that the growth of profit sharing as applied to rank-and-file workers has practically been abandoned in America. The conviction has grown that, while profit sharing may be an excellent arrangement as applied to persons of some responsibility, it has comparatively little effect on the rank and file, and is always in danger of creating ill will when a period of low profits or of no profits arrives.

Incentives, which are based on the actual output of the individual and an extra compensation paid very shortly after the production period has been completed, have in large measure taken the place of profit sharing as applied to rank-and-file employees.

Compensation of Executives. In the days when ownership and management were almost inseparable, the compensation of the manager was equivalent to the profits of the business, but with the practical divorce of management from ownership which came with large-scale industry and the development of the corporation, the first tendency was to put the manager on a salary, his dividends from stocks comprising a comparatively small part of his total income. There were, of course, many private "deals" in which the

manager was paid a salary and received as additional compensation either a bonus based on profits for the year or the dividends on stocks which were assigned to him and which by good management he might make extremely valuable. These cases applied, however, chiefly to the president or general manager of a company.

In recent years there has been a distinct tendency toward applying the principle of extra incentive to other executives—factory managers, district sales managers, the foreman and other supervisors, and even to staff men—the result of whose efforts it is usually comparatively hard to measure.

Some of these plans take the form of the more or less old-fashioned profit-sharing plan. In general the tendency, however, has been to base the extra compensation, so far as possible, on a measurement of the results of the efforts of the particular individual. The net result of this departure is to reintroduce into large-scale business in America some of the elements of incentive which were general when business was small and when the manager was also usually owner and thus had a direct interest in the business.

Hours of Work. The work time per day and per week has been decreasing in America over a long period of years. One of the greatest issues of public importance was the steel industry's twelve-hour day, which three years ago became a thing of the past. The elimination of the twelve-hour day in the steel industry does not seem to have in any way justified the alarming predictions which some persons were disposed to make. In fact, there were many people in the steel industry who believed that it could have been done long before.

During the last few years the most significant occurrence was the adoption of the five-day week by the Ford Motor Company and the growth of a good deal of propaganda in favor of the general spread of the five-day week. There has been comparatively little evidence that the movement is spreading widely but there are those who predict that five or ten years from now the five-day week will be as general then as the five-and-a-half day week is today.

Vacations for Manual Workers. Vacations with pay for executives and office workers have long been general, only a comparatively small number of companies holding out against vacations with pay for office workers.

More recently vacations for manual workers have become more general. In some quarters the opinion is held that this vacation with pay increases the loyalty and efficiency of the worker and that it pays profits to the company even though it does somewhat upset the production schedule. A great deal depends upon the character of the industry and the custom of the community.

It may fairly be said that, while there is no well-thought-out attitude on the practice of vacations with pay and that the practice is more or less a matter of expediency, nevertheless it is probably gradually becoming an unwritten part of the contract of employment.

No American state has made vacations with pay a legal requirement. Even in Canada, where this step has been agitated by labor organizations, no such action has been taken, nor is there any likelihood that such legislation will be passed in view of the rapid spread of vacations with pay.

Pensions. Pensions have been rapidly becoming a part of the industrial fabric of America, at first slyly in the form of informal pension plans in the

nature of special treatment of individual cases, and later more openly through the adoption of formal pension plans. The topic is subject to a great deal of dispute, and some companies, which established pension plans some years ago on a rather liberal basis, are beginning to find that the accumulating pension cost is much higher than they had anticipated. The tendency now is, partly in order to keep down the pension cost of companies, to put pension plans on a contributory rather than the non-contributory basis on which most of the earlier pension plans were based.

Stock-purchase and Savings Plans. A good many companies have provided for the purchase of the securities of the company by the employees. At first such plans were established largely in the expectation that they would increase the loyalty and the efficiency of the employees by giving them an interest in the company. Some of these plans were very generous, the company in many cases making a partial contribution.

More recently, the emphasis has been placed on the thrift and savings aspect of the purchase of company securities by the employees, and the contemporary stock-purchase plans have therefore taken on a somewhat more conservative aspect.

One large company has established what is practically an investment trust, an affiliated securities corporation, the shares of which employees buy. The securities corporation in turn purchases a variety of securities, including the bonds, preferred and common stocks of the manufacturing company, as well as the securities of other companies.

Insurance and Benefit Plans. Group life insurance has been one of the substantial developments of the last ten years. Altogether there was approximately \$6,500,000,000 of group life insurance in effect at the beginning of 1928. At first, a large proportion of group life-insurance plans were non-contributory—that is, the company paid the whole cost—but more recently there has been a very strong tendency toward having the employee share in the cost.

Similarly, there has been a decided growth of benefit plans, a movement which began earlier than did group life insurance. These benefit plans provide a scale of benefits for certain disabilities including accidents, sickness, and death. In many cases they exist side by side with group life insurance. In other cases they are more or less a substitute for group life insurance. As in the case of group life insurance, there has been a movement toward requiring contributions from the company and also toward the administration of the mutual-benefit fund by an employees' committee with the advice and cooperation of executives of the company.

Vocational Adjustment. The importance of the preparation of job descriptions and job specifications has been much discussed, but until recently the discussions had not led to much definite action, the logical step following job analysis. Such specifications are essential for any plan of job classification and salary standardization. One distinct tendency in job analysis is the setting-up of a statement accentuating the "job difficulties."

The introduction of new employees to their jobs, especially to the foreman and to the fellow workers, and to their environment is being performed more effectively than ever before with distinct advantage not only to the company

but also to the employee. Increased output and increased earnings during the initial period of employment and reduced turnover among new employees are the results to be gained.

Gradually the idea of transfers and promotions from within the organization is spreading, without, however, taking the form of a rigid rule which prevents the recruiting of necessary specialists from outside the organization.

The rating of rank-and-file employees, which was much practiced some years ago, has largely been eclipsed by the growing attention to the rating of persons of possible eligibility for promotion to executive positions of greater responsibility.

Promotion within the company is a policy adopted by a few companies with good effects on the morale of the organization.

Health and Sanitation. Promotion of health and sanitation has probably been the least effective of all movements in personnel administration, but this is a subject which is beginning to attract a great deal more attention. The costs to the company and to the employees of ill health, consequent absence from work or inefficiency on the job, are regarded by many as vastly more important than the accident problem to which a great deal of attention has been given in the past.

In nearly all large companies medical examination prior to employment is the rule, but compulsory periodic medical examination for those already on the payroll has not yet been generally adopted. There are some companies following this policy and they are emphatic in their praise of it, claiming that it has been attended by no serious complications or objections on the part of employees.

In most companies, however, emphasis has been placed on health education rather than upon compulsory examination, and the general practice has been to concentrate not so much on the rank-and-file employees as upon the supervisors, who in turn carry the message of the health program to the employees. This is another good illustration of the advantages of a decentralized responsibility in personnel administration.

Safety. Because of the spectacular losses resulting from industrial accidents, a great deal of effort has been expended on reducing the number and seriousness of such accidents. Workmen's compensation legislation has been passed in all but three of the states, and safety work is vigorously promoted in many companies both large and small.

Results from this phase of industrial-relations work can be isolated more easily than from any other, and this very quality of tangibility has undoubtedly had a great deal to do with the interest shown in accident prevention. Certainly the record of accomplishment is so remarkable, in companies where sustained and intelligent effort has been made, that it should serve to convince any set of officials of its value.

Figures issued yearly by one large corporation indicate what can be done. From 1906 to 1926 serious and fatal accidents decreased 60.22 per cent, and from 1912 to 1926 disabling accidents (including all accidents with loss of time greater than the working turn) were reduced 83.81 per cent. This decrease has been concurrent with a marked expansion in properties and in numbers of employees. The results have been accomplished by careful

engineering, which has removed physical hazards in the plant or on machines; by keeping complete records of accidents subdivided by cause, which indicate where added precautions are necessary; and by a ceaseless campaign of education. Each is necessary; but perhaps the educational campaign has yielded the greatest returns.

About \$20,000,000 has been spent on accident prevention since Jan. 1, 1912. Had accidents continued at the 1906 rate, however, far more would have been paid out under the various state compensation laws to the injured and their families. If, as a large insurance company recently stated, it is true that to every dollar of compensation cost resulting from an accident must be added \$4 to pay for lost time, labor turnover, waste of materials, interference in production, and other conditions arising out of the accident, the saving from accident prevention is many times greater.

While for some years safety education was directed largely toward rank-and-file employees, it has been found by another very large company that still greater improvement can be made by concentrating the safety educational personnel activities and of carrying out the personnel program through and by the line organization.

Service to Employees. In the early stages of the personnel movement in America, a relatively large proportion of attention was devoted to what was called welfare work, comprising such activities as social clubs, recreational activities, camps, athletic activities, employee publications, company stores, sales and discounts for company products, legal aid, housing, and restaurants.

Probably as much is done by companies today as formerly along these lines, but this general group of personnel activities is much less conspicuous because it is being overshadowed by many newer and relatively more important activities.

There has also been a tendency to eliminate certain classes of personnel service and to continue only those which have a direct bearing on the efficiency of the employee, his earning capacity and, by implication, his value to the company.

Other activities which have a much less direct bearing on the company's interest are being turned over more and more to actual administration by the interested employees themselves, and many of these are financed almost entirely by the employees. This gives employees an increased measure of autonomy and a more self-respecting status. This tendency is a good illustration of the trend away from a paternalistic attitude toward employees.

Joint Relationships. The term joint relationships is used in the United States to designate the dealings between management and employees on matters of mutual interest, particularly as affecting such vital subjects as wages, hours, and working conditions; discipline and grievances; and efficiency and economy of operation. In industries in which employers recognize trade unions, joint relationships usually are handled between the management and the union organizations. Union contracts customarily cover wages, hours of work, and general conditions in the shop, and occasionally they include agreements for the mediation or arbitration of disagreements, for unemployment insurance, or for other subjects outside the routine of ordinary

union negotiations. There has also grown up in some industries a system of union-management cooperation, having for its purpose joint endeavors toward the promotion of operating efficiency, the reduction of costs, and the building-up of morale.

Employee Representation. Perhaps the most impressive development of recent years in connection with joint relationships in American industry is employee representation. Under this classification are included all formal agreements for direct dealing between management and representatives elected by and from the employees in an individual company or plant.

The representation movement as a conspicuous part of industrial management dates from about 1915 and the period of its greatest growth did not begin until after the United States entered the World War. In the period of business depression beginning in 1921, a considerable number of plans were abandoned, but in the last five years representation has shown a steady growth.

Under the typical plan of employee representation the workmen of a single company elect representatives from among their own number, usually by voting districts arranged in such a way that each representative has for his constituents fellow workers with whose conditions and jobs he is intimately familiar. These employee representatives deal with representatives of the management through joint conferences and joint committees and in other ways. The authority of the shop committees or works councils and the scope of subjects which they are authorized to consider vary in the procedure of different companies. While in a few cases, employees are prohibited from joining unions or from joining a particular union that has been in active opposition to the employing company, it is usual for a representation plan to provide explicitly or tacitly for the indiscriminating employment of union and non-union men.

In addition to the organized practices in joint relationships that have been discussed, there are many less formal methods of dealing with subjects of mutual interest. In some companies the approach of the employees to the management is limited to line officials, with whom the individual workman is required to take up grievances or suggestions. In others the personnel department functions as the point of contact between management and employees. There are infrequent cases in which members of the company's boards of directors are elected by rank-and-file employees.

An important function of any procedure in joint relationships is the exchange of information and opinions between management and workpeople. Sometimes this is effected through a representation plan or an agreement for union-management cooperation, sometimes through employees' newspapers or other plant publications, and sometimes through more or less formal suggestion systems under which workmen are encouraged to submit to the management their ideas as to improving conditions or methods of operation. Usually these suggestion plans include the payment of awards for valuable ideas that are adopted.

Interest in Personnel Administration Growing. In the last few years there have been times when, on the surface, it might seem as though the personnel movement in America had received a setback. This impression was caused

largely by the fact that at various times there seemed to be an unusual number of personnel men looking for positions. It may be stated that there is vastly more interest in personnel administration in America than ever before and that this interest is on a sounder basis. For some years it was difficult to the factory manager or the president or other line officials to take an interest in personnel problems, the inclination being to refer all such matters to the personnel man. With the growing recognition that personnel administration on a sound basis has a definite relation to the business success of the organization, a good deal of this former indifference has disappeared.

Furthermore, it is being recognized that sound management has a very definite relation to the interests of the employees, and that the introduction of effort-saving machinery and labor-saving management and the development of better morale almost inevitably result in greater output as a result of which the employees receive increased earnings.

An interest in personnel administration has become an eminently respectable subject for discussion in business meetings, especially as the subject-matter is approached in terms of management. Indeed, it would be practically impossible to keep the subject of personnel out of any meeting of executives discussing almost any management problem, whether it be a meeting of treasurers or comptrollers at a conference on financial management; of factory executives at a conference on production; of sales executives at a conference on marketing; of office managers discussing office management; or at a round table of presidents discussing problems of general management.

What appeared to be a period of declining interest in personnel administration from approximately 1920 to 1924 may now be interpreted as a period of transition which has led to a sounder concept of the function of personnel activity in the management of the concern and of its relation to the welfare of the community at large.

CHAPTER II

BUDGETING PERSONNEL REQUIREMENTS

BY CHESTER P. GRASSMUCK, *Department of Planning and Research,
Philadelphia and Reading Coal and Iron Company*

Budgeting is a method of planning operations and measuring the financial results by a coordination of all the functions and controlling the actual performance obtained by means of a periodic comparison with the standards set up. It is a means by which general executives may express their ideas of policies as to their respective functions. It is no alchemy or panacea which, when once developed, will permit the executive to sit back in his chair and let the budget do the rest. It is a means of securing control of an enterprise based on a prearranged plan or program for a definite period.

The successful operation of a budget system of control depends to a great extent upon the ability of the management to enlist the cooperation of every employee in a supervisory or managerial position. These men may be willing to estimate operations for a future period, but unless they cooperate to the fullest extent to keep the actual performances within the budget, the real purpose of the budget, namely, the control of every phase of the business to secure the most economical operation, will be defeated.

The pay-roll budget is a big step forward to that end if, at the beginning of the year, instead of entering the new period without some definite plan of growth, a program is set up which clearly outlines the policies to be followed as to personnel and pay roll.

A good pay-roll budget makes possible a consistent policy with respect to employment and wages or salaries of working forces. It also makes possible the handling of these forces intelligently when a reduction or increase in business is anticipated.

Organization of the Company. It may be asked, Is any special form of organization required for the installation and operation of a pay-roll budget? In every company some individual is responsible for the various functions. In some enterprises these functions may be performed by one individual, in others the responsibility for each function is delegated to subordinates. No matter how complicated the organizations may be, analysis will reveal the simple fundamental skeleton on which to base the procedure.

The following pay-roll budget procedure is applicable to an enterprise producing its own raw materials, transporting them to their manufacturing plants, manufacturing the finished products, selling these products, and transporting them to the purchaser. Such a company would probably be organized somewhat like the organization chart in Fig. 1.

Installation and Procedure. *a. Organization.* It is a common practice in budget work to establish committees for each type of budget, however, due to an unfavorable experience with the results achieved by too many committees it is suggested that the educational work be direct, either in talks or propaganda written for the purpose of securing the success of the budget program and that budget committees be limited, the secretary to be the man responsible for the installation of the budgetary program.

FIG. 1.—Plan of organization of XYZ Oil Company and subsidiaries.

b. Forms and Instructions. In the case cited above, to the secretary is delegated the actual work of preparing forms, procedures and instructions. His first step is to examine all personnel records and prepare a form which is acceptable to the comptroller and to the operating executive in that it is all inclusive and from the administrative viewpoint, in that it gives the information required to control this phase of the business.

In order that managers have a clear understanding of the way to complete these forms, instructions are prepared in detail explaining exactly what is to go into each column and opposite each classification. All forms and procedures are to be approved by the budget committee.

As an example of such study various forms are shown and we shall follow through the procedures of their preparation. A sample of explanatory instructions follows:

Pay-roll Budget

XYZ Oil Company

Aug. 22, 1930

- Purpose:** To set up the estimated pay roll for the last three months of 1930.
- Preparation:** This information is to be prepared by companies by the planning and control division of the operating and construction department under the supervision of the superintendent, who should be furnished forms, explanations and any other information which will be a basis for the preparation of the estimates required.
- Units:** Columns a, c, and g and columns b, d, and h, should be expressed in number and value respectively. All dollar figures on this report should be expressed to the nearest hundred, for example, \$6,749 should be expressed at \$6,700.
- Basis:**
1. Preliminary estimates (various).
 2. Past performance.
 3. Contemplated plans and policies of the company for the budget period.
- Explanation:** The following columns are to be filled in by the planning and control division.
- Columns a and b** Show the actual performance in number and dollars respectively for the last three months of 1929.
- Columns c and d** Show the preliminary estimate in number and dollars respectively for the last three months of 1930.
- Column e** $(\text{Col. c} \div \text{col. a}) - 100 = \%$
- Column f** $(\text{Col. d} \div \text{col. b}) - 100 = \%$
- One place beyond the decimal point is sufficient, i.e., 20.5 %.
- The following columns are for the use of the New York office and should not be filled in.
- Columns g and h** Show the approved budget in number and dollars respectively for the last three months of 1930, as set up by the budget committee.
- Column i** $(\text{Col. g} \div \text{col. a}) - 100 = \%$
- Column j** $(\text{Col. h} \div \text{col. b}) - 100 = \%$
- One place beyond the decimal point is sufficient, i.e., 20.5 %.
- In preparing the various classifications as outlined, the following points and procedure should be considered.
- The pay-roll budget includes the wages or salaries of the personnel devoted to the refining of crude oil and products, and the manufacturing of gasoline; those required to perform the supplementary or service operations in refining and manufacturing; and those involved in the administrative functions.
1. Present status of personnel.
 2. Changes in permanent personnel, such as additions.
 3. Temporary personnel to be taken on during peak periods.
 4. Salary revisions.

1. The form shown in Fig. 2 covers a section of one department, such as the voucher section of the accounting department as shown in the organization chart in Fig. 1.

2. The form shown in Fig. 3 covers departments, divisions or companies.

3. The monthly break-up of the first two forms is shown in Fig. 4.

Preparation. a. Organizing. Some one individual must be responsible for the operation of the pay-roll budget. However, this does not mean that the entire responsibility for its working is to rest upon one individual, but rather, this person is to act as a clearing house for matters relative to the operation of this budget.

Every individual who is charged with the responsibility of supervising personnel shall be required to assist in the preparation of the pay-roll budget. The major executives should not be asked to study many details which the

general executives should work out in preparing this budget. He must receive, however, the budget in a form that will give him a comprehensive and composite picture of each department in his unit so as to be in a position to give department heads the benefit of his advice and counsel resulting in a program which is in entire harmony with his judgment and the general plans of the company.

If this cooperative functioning between major and general executives is feasible, then the same procedure should be followed in each unit down the line of organization, namely as shown in the organization chart, division, departments, sections, etc.

Experience proves that the best results are obtained when the original estimates are prepared by the persons who are later to be held responsible for the execution of the estimates, thus each manager will have the composite picture of the requirements for his unit.

b. Estimates. Companies having complete budgetary programs have source for the data in their various expense budgets, such as general expense,

operating or manufacturing expense, etc., where all items of pay-roll must be classified in the same way as in the pay-roll budget. The pay-roll budget in such a case is merely a statistical summary which grows in importance in proportion to the size of the company using it.

After the preliminary estimate for each division and subsidiary has been considered and approved by the budget committee, they are returned to their source and become the working program or policy for the various sections and departments as regards to personnel and pay-roll. In no case should

the budget be considered as iron clad but can only be revised on the approval of the budget committee, in such instance the revised budget follows the same procedure as the original estimate.

Periodic Reports. The tendency in most organizations is to expect the supervisory head to operate his unit efficiently without knowing the results

FIG. 5.—Form showing estimated and actual performance.

obtained. Experience proves that the more a man learns about the details of expenses and costs within his unit, the better qualified he will be to reduce them, with the broadening effect of causing him to see the relation of his unit to others.

Periodically and according to a definite program, reports showing the actual results in comparison with the budget and past performance must be prepared. Many attempts at budgetary control have failed because the importance and necessity of checking the execution or actual performance of the program against the budget was not realized. The set-up of these reports must not necessarily vary from the forms used in the preparation of the estimates. The classifications should remain the same but the columnization includes estimated and actual performance as suggested in Fig. 5.

The respective information shall be compiled by sections and departments, divisions and companies in the same detail in which the budget is set up.

Advantages. With this plan established we find we have experienced these advantages:

1. Every one is required to think his function through to the end.
2. Executives are compelled to think of their work from a strictly business standpoint and to make such plans for the future as will fit in with the program of the management. Having studied their functions they will instinctively try to beat their estimates, which means they will continue to study and show immediate improvements.
3. It gives authority with responsibility in that it enables the division, department and section heads to understand and be responsible for the number of employees and the pay-roll expenditures within their unit.
4. All individuals in managerial or supervisory positions share the responsibility with each other by having the budgets on a departmental basis. The old army game of "passing the buck" cannot exist.
5. It gives a check on the operating efficiency of each department through the knowledge which it supplies the executive of the predetermined operating requirements and the actual expenditures for the period.
6. It increases the interest of the entire supervisory organization of a business and unites their efforts in a common endeavor to secure greater operating efficiency.
7. It sets up the requirements of all units of the business. By careful planning the demands for increased number of employees can be anticipated, thereby avoiding the disturbances arising from misfit employees.
8. By analyzing personnel and pay-roll according to the classification shown on these forms, it provides information or standards which may be used by the salary committee in comparing the various classifications between all subsidiary companies and between units within the company.
9. Every one in a managerial or supervisory position feels he has had something to say in the management of company affairs, has given his views as to policies, has established a goal for his unit and knows his plans for the period.

Briefly, it makes possible the forecasting of labor needs and costs, the control of labor cost, the placing of responsibility for labor cost, and an incentive to department heads to reduce and control costs. Budgets, no matter how complete, can never be a substitute for management. When a man has been given a job, he should be supplied with the tools with which to do that job.

The results which one of the larger corporations in the country obtained from a pay-roll budget installed as of Jan. 1, 1924, will exemplify the value of the method. During the year their total volume of sales increased 18

per cent; they reduced their total pay roll 12 per cent and the average individual salary increased 5 per cent. This material satisfaction was not the only result. Better salaries brought better workmen into the company, with the natural result of raising the standards of workmanship and increasing the output and sales; finally, the ultimate result of the profits to the company and all individuals—a perfect circle of good management.

CHAPTER III

MAINTENANCE OF THE WORKING FORCE

RECRUITING PERSONNEL

By W. C. BOWEN, *Personnel Manager, International Telephone and Telegraph Corporation*

One of the absorbingly interesting problems of present-day management, the manifold task of maintaining an adequate working force, resolves itself into the following principal divisions:

1. Recruiting the personnel supply, including an evaluation of sources both within the organization and without.
2. Preparation of job classifications or specifications for assistance in recruiting; in other words, securing a knowledge of job requirements.
3. Selection of applicants who fulfill the requirements of the job, having in mind the physical, mental and temperamental qualifications required.
4. Introduction of the applicant to the job and systematic follow-ups.

Placing of Responsibility. The work of recruiting and selecting personnel is generally delegated to some specific individual or department. In an interesting report on Industrial Relations in the Metal Trades, prepared by the committee on industrial relations of the National Metal Trades' Association in 1929, it was found that of approximately 1,000 plants in the metal trades, 227, or 25 per cent, have centralized employment departments; 455, or 50 per cent, delegate employment to a specific individual; 220, or 24 per cent, leave employment in the hands of departmental foremen. It cannot be assumed that the practice of hiring new workers in the metal trades is indicative of the practice of industry as a whole, but the percentages shown above are of startling interest. Many large, medium sized and even small companies have seen the advantages to be derived from organizing a centralized employment or personnel department to function in the selection of employees. However, whether there be a centralized employment office, a specified individual, shop foremen or office supervisors in charge of this important function, their responsibilities should be clearly defined and definitely understood by the rest of the organization.

Limitations of Personnel Policy. The individuals to whom this work is entrusted should be thoroughly conversant with whatever restricting limitations the management may wish enforced. These limitations may cover a number of factors such as education, citizenship, or distance from plant or office. Some concerns definitely stipulate that they will employ only work-

men residing in definite localities; others stipulate that their workmen must be American citizens.

Job Classifications and Specifications. In the process of preparing job classifications or specifications to assist in the selection and maintenance of the working force, the promotional possibilities of various jobs should be kept in mind. When vacancies occur it is frequently possible through the assistance furnished by these job specifications to locate candidates in the organization who may be in line for the vacancies. Such procedure forestalls any possible criticism employees might have that they were not being considered for promotion when vacancies occurred which they believed they were qualified to fill. Frequently whole series of promotions within the company can be worked out when a vacancy occurs with little or no additional expense to the company. Those companies which have made a careful analysis of the requirements of the jobs in their organization and which have definite training programs and a thorough promotional procedure find it easier to attract a better type of worker to their organizations. Their reputation for fair dealing and sincere interest in the progress and development of their workers spreads quickly.

Selection of Applicants. When it is not possible to fill vacancies in the staff from within the organization, it is necessary to select the best qualified applicants obtainable from the labor market. The technique of selection varies widely in different companies. The individual or department responsible for this function must know where to go to find the best qualified applicants and once the correct source is found, the machinery of selection starts in motion. After preliminary interviews are given, the survivors of these interviews are requested by some companies to take a series of tests to determine their various abilities and aptitudes for the openings in question. Many concerns request applicants to take physical examinations and make a thorough investigation of their references before deciding upon their employment. It is needless to say that the spirit with which the members of this department do their work is of greatest importance. Applicants should be courteously received and given every consideration possible irrespective of whether there is an opening for them or not.

Sources of Supply. Chief emphasis in this article will be placed upon a review of the various sources of supply to which companies may go to replenish their working forces.

Job Seeker. Possibly the most common and fruitful source of labor supply is the job seeker who applies at the employment office in person. He may have been attracted to the company because of its good reputation or because friends of his worked there or he may be a professional job seeker. The quality of this supply depends to a considerable extent, as intimated above, upon the reputation of the company in the community. The amount of this supply predicates a considerable idle surplus of applicants from which to select. This supply is naturally greater in times of unemployment than during boom periods. If these job seekers are carefully interviewed and applications accepted from those whose qualifications merit careful consideration, many of the openings which occur in the company can be satisfactorily filled by these applicants.

Letters of application are a good medium through which to obtain workers. This source of supply should be cultivated by the acknowledgement of all letters which are received, informing the writers as to the possibilities of their present or future employment. Where it appears that the qualifications of the writer indicate that he is a candidate for consideration, a good procedure, provided a personal interview cannot be readily arranged, is to forward an application blank with the request that it be returned together with a snapshot or photograph, if possible. If the application appears favorable, the applicant can be requested to call for an interview either at his own or company's expense.

Friends, Relatives. Still another source is the friends and relatives of present employees, stockholders, directors, customers, and others personally interested in the company. Some companies have a definite policy not to employ relatives of present employees. There is more justification for such a policy in a small firm than in one of greater size.

Ex-employees. Employees who have previously worked for the company and who have been released due to lack of work are often a good source of supply. Their records are generally on file in the employment office, so that the company can be fairly certain regarding their work performance.

Office Appliance Companies. Favorable consideration should also be directed to office appliance companies such as the typewriter, comptometer, and accounting machine manufacturers who maintain employment bureaus to supply skilled operators to their customers.

Hospitals and Penal Institutions. Many factories use hospital and penal institutions as a source of supply. Frequently, employees who have been injured are available for new openings upon their release from hospitals. Likewise ex-criminals are a source to be considered. Many concerns feel a sense of public duty in employing a certain percentage of these men, thus aiding in their rehabilitation.

Advertising. Another source for recruiting personnel is through the medium of the advertising columns of newspapers and trade journals and also by the use of circulars and posters. Before placing advertisements, a careful analysis should be made of the facilities of the different newspapers and journals, as some advertising mediums are better for certain classes of help than others. Advertisements should be brief, specific, and well set up. Insistence on favorable locations in the various media employed is important. Moreover, advertisements should be inserted on days when they will bring best results. A careful analysis of results over a period of a few weeks will indicate which days are preferable for advertising.

Employers in search of additional personnel can profit from a careful study of the "want ad" columns in the newspapers, as these often bring to light desirable applicants. Frequently, applicants who advertise in the want ad columns are of higher grade than the casual applicant who applies at the employment office. If these advertisements are of interest, postal cards can be sent with the request that the applicants call for an interview.

When placing advertisements, a choice must be made between open and blind advertising. When open advertisements are used, and it is preferable not to have large numbers apply in person, applicants can be instructed

in the advertisement to write, rather than apply in person. In the case of specialized positions it is frequently better to insert blind advertisements, although there are certain disadvantages in this, one being that those who are employed in responsible positions often hesitate to answer blind advertisements for fear the advertisements may have been inserted by the concern for which they work.

Circulars and posters are used by factory executives to obtain additional workers, especially in periods of scarcity of labor. These mediums often bring immediate results. It is customary to have employees take the circulars home and pass them out among their friends and neighbors. Street car posters, signs in windows, and bulletin boards are also employed.

Schools and Philanthropic Agencies. Other profitable sources of supply are the high schools, trade, commercial, and business schools, vocational guidance bureaus, Y.M.C.A.'s, Y.W.C.A.'s, churches, lodges, and trade unions. A company eager to secure the best grade of personnel for junior positions makes it a point to keep in close touch with sources of this type. Many concerns invite school teachers and superintendents to the company's plant or office to inspect the working conditions and meet the supervisory staff. They supply the schools with printed literature regarding company activities. Where such personal contact is maintained, better results in the way of personnel can be expected.

Colleges and Universities. An advantageous source of supply for personnel of the higher grade are the academic, business, and engineering colleges and universities. Various concerns have developed a high degree of skill and technique in recruiting college graduates for work in their organizations. It is generally recognized that these men are a distinct asset to any company, provided the right type is selected and given adequate training and supervision after employment. The general practice in carrying out this recruiting is to make arrangements with the colleges and universities for the visits of scouts and recruiting agents well in advance of the time of their scheduled visits. Upon their arrival at the colleges, the personnel offices place the students in touch with these representatives at which time the opportunities open to the students are discussed. The degree of success obtained in securing representative college men depends to a great extent upon the ability of the men representing the companies in judging men and interesting the students in the advantages and opportunities open to young men in their organizations.

Scouting is still another method followed in obtaining workers. Rural districts, foreign language groups, recent immigrants, and boarding houses are common sources from which the scout seeks his men. Scouting is resorted to for the most part in times of stress when labor is scarce. It is not looked upon with any great degree of favor by employers, as it often results in taking workers away from competing companies. Scouts are frequently sent to distant cities to recruit labor. When this is done, it is important that men employed by this method be familiar with the terms of employment, working conditions, wages, terms of contract, and other essential details. Failure to give applicants this information often results in misunderstandings and consequent resignations.

Public and Private Employment Offices. One of the most widely patronized sources for securing workers is the public, private commercial and private non-commercial employment agencies. Patronage of these offices varies in different localities and cities, depending to a considerable degree upon the efficiency and reputation of the agencies is question. Both types of offices have their ardent supporters and also their severe critics. Considerable criticism has been launched against the public and private commercial agencies for various reasons. One of the principal objections to the public agency has been that the majority of offices have been operated inefficiently. This can be explained to a considerable degree by the lack of adequate appropriations to carry on the work effectively. Managers have been underpaid and poorly trained and their offices have not been well maintained. In most instances the better type of applicant has not made it a practice to use the services of the public offices, believing that these offices could not offer them attractive jobs or materially assist them in their search for work. Employers as a rule have not used the services of these agencies knowing the unsatisfactory conditions existing in most of them. The success of these public offices depends on the wholehearted cooperation of employers and, when this is lacking, little progress can be made.

Notable work has been done by the Cleveland public employment office. This office has succeeded in securing the cooperation of all types of employers in Cleveland and has successfully served as a clearing house for all types of workers in that city. The experience of this office demonstrates the fact that these public offices can obtain good results if they have the wholehearted cooperation and confidence of employers. This cooperation is not likely to be forthcoming, until the operation of these offices is removed from the realm of politics and until steady appropriations are guaranteed.

With reference to the organization of the labor market, there is reason to hope that within the next decade or so we shall have a well-organized system of national public employment offices throughout the country, cooperating closely with existing state and municipal offices. Such a system would afford an opportunity to transfer unemployed workers from sections of the country where there is a dearth of jobs to sections where jobs are more plentiful. In other words, it would make possible a continuous redistribution of the labor supply, as a result of having at hand centralized information covering the various sections of the country. The system would operate in a manner similar to the Federal Reserve System in the field of finance. The organization of such a system could be made to supply much needed data on employment statistics and economic conditions in various sections of the country.

Private non-commercial agencies, such as those of trade associations, trade unions, and seamen's unions are operated for the benefit of employers and workers alike. In addition to these are the fraternal, religious, and benevolent institutions whose prime reason for being is to serve needy individuals who come to their attention.

Private commercial agencies are extensively used, especially in large cities where office and salaried help is required. They also compete with the public employment agencies in supplying common labor and shop workers. Many agencies of the latter type have contracts with the various railroads

under which they guarantee to supply a certain number of men to the railroads each month. These agencies also supply lumber, farm, and harvest workers. Many abuses have crept into this type of agency and the various states have found it difficult to control agencies of this type which violate its laws.

Many of the higher grade agencies of the commercial type are doing excellent work in supplying the needs of employers. In New York, for example, there are few large firms which do not contact with certain picked agencies when there are positions to be filled. Certain executives are not willing to use the agencies when looking for executive material, but there are many others who do make use of their services.

Unfortunately, private agencies, especially those dealing with manual labor, have been criticized for glaring abuses. They have been accused of misrepresentation of jobs, sharing fees with dishonest foremen, making a high labor turnover profitable for both the agent and foreman. They have likewise been accused of refusing to return fees to applicants who have failed to secure work through them. Frequently, the immediate interests of private agencies have been directly contrary to the interests of industry and the community.

Probably the most common complaint lodged against the private agency is its lack of discrimination and failure to exercise judgment in supplying the needs of employers. It is a common practice for these agencies to send large numbers of applicants to employers with the hope that one of them will have the qualifications necessary to fill the job. However, if the employer warns the agencies against such procedure and gives definite specifications of the opening to be filled, this difficulty can be minimized, if not entirely eliminated. The fault does not all lie at the door of the agency. The employer all too frequently is vague in describing the qualifications which are required and forces the agency to rely upon its own judgment. Some employers fail to play a square game with the agencies and should not be surprised, if the agencies follow the same tactics in dealing with them.

Although a number of European countries and five Canadian provinces have prohibited the operation of fee-charging private agencies on account of the grave abuses of this type of agency, there is little likelihood that such action will be taken in the United States, at least for many years. The Supreme Court in passing upon a New Jersey law regarding private agencies ruled in 1920 that the regulation of fees of a private employment office was unconstitutional, because this business is not affected with public interest sufficiently to warrant the fixing of charges. A state may not prohibit the existence of these agencies within its borders, although in Wisconsin and New Jersey state officials may refuse applicants for licenses, if it is deemed that adequate placement agencies already exist. It has been recommended as a general procedure by those interested in regulating private agencies, that the character of the applicants for agency licenses be thoroughly investigated before the licenses are granted; that the suitability of the proposed premises of the agency requesting the license be examined and the need for such an agency in the community be reviewed. Certain states have definite legislation covering one or more of these points.

The fee-charging agencies have a legal existence in the United States. From a practical and reasonable point of view, they will undoubtedly continue to thrive. They serve selected types of workers and professions with greater efficiency than do the public employment offices at the present time. They perform an economic and valuable service to the job seeker and as long as they continue to function efficiently and satisfactorily, there is undoubtedly a place for them in our system of society.

Introduction to the Job. Nothing has been said thus far regarding the fourth point raised in this paper, the introduction of the applicant to the job and systematic follow-ups. It goes without saying that once the worker is hired, the most important problem is to adapt him to his job and thus eliminate unnecessary turnover. Success in accomplishing this hinges upon the proper classification of jobs, the formulation of definite lines of promotion and the ability to judge workers according to their qualifications and merits. The job of securing competent workers will be simplified and made easier for every company which establishes and maintains proper standards of employment, hours of labor, safe and sanitary working conditions. Such companies need show less concern about their problems of securing competent workers, as their reputation for fair dealing will attract to their employment offices sufficient workers with qualifications of the sort to satisfy most of their needs.

THE EMPLOYMENT INTERVIEW¹

By V. V. ANDERSON, M. D., *Director of Employment, Placement, and Personnel Research, R. H. Macy & Co. Inc.*

Function of the Interviewer. It is the function of the interviewer to bring together, analyze, and digest all of the information that bears upon the suitability of an applicant for a given job as well as his general value as a personnel risk for other possible positions. He sums up all of this information into an individual diagnosis and decides to employ or reject the given applicant. The interviewer, himself, is the most important element in the entire employment situation. His knowledge, experience, interviewing technique, and diagnostic ability become the index to the quality of personnel employed. Tests and other tools to be used can aid and guide him in getting a better knowledge of certain aspects of a given applicant's abilities but they will never alone and of themselves furnish sufficient information to afford a safe basis for securing employees, for they do not evaluate the personality. His special training and experience should have given him a clinical knowledge that forms the background for understanding the physical and mental factors that underlie faulty human adjustments bringing about failure at work or failure in other life situations. This knowledge constitutes an understanding of the personality, a diagnostic acumen that enables the interviewer to make satisfactory estimates of the possibilities in any given applicant for successful adaptation to work.

¹ Taken by permission of the publishers from "Psychiatry in Industry," Harper & Brothers.

If sound progress in employment work is to be attained, we must cast aside theories of inborn, mystical ability to "size people up" or "to read character." What all honest investigators are after is a discipline that presupposes a knowledge and a technique—a discipline that offers something more solid than guesswork.

The issues involved in work adjustments do not differ in their fundamentals from those underlying behavior problems in other walks of life. These issues can be approached in the same scientific spirit that we have sought to understand natural phenomena in general. Long since have we discarded the idea that behavior disorders, either of children or of adults are not amenable to an acceptable scientific method of inquiry. We are forced to deny the fact that people are just good or bad employees and that by some trick method the sheep can be picked out from the goats; nor do we stand any longer for the belief that there is no known way of ever telling just how an applicant will behave in a given job situation. That these things can be investigated and fairly well understood and that they can be approached in the same scientific spirit of study that we have sought to understand other human problems is now an accepted fact.

It has seemed that there was a gulf between the practical, "hard-boiled," experienced man of business with a good common-sense background who does the employing, and the laboratory psychologist whose exact methods of measurement will have nothing to do with the shrewd "hunches" of the practical man. The first in his attitude toward scientific method oscillates between a naive gullibility—swallowing hook, line, and sinker—and open resistance and antagonism. On the one hand, we find employment people who expect a simple intelligence test to select good employees for them, as though the matter of cleverness or smartness was the principle determining factor in work success. While, on the other hand, we find interviewers who will have nothing whatever to do with the whole thing, due either to a misunderstanding of the use of such methods or to prejudice against a technique in which they themselves are not trained. In other words, the average interviewer does not utilize the psychological test at its proper value.

The industrial psychologist in his ambition to settle at one blow all employment problems has sadly oversold the matter of psychological tests or himself has misunderstood their limitations, inasmuch as he too often leads the layman to feel that the psychological test itself is the selective agent. The fact is that neither one of these groups is wholly right or wrong. The interview if properly conducted and intelligently interpreted opens up knowledge concerning the applicant's past history and ways of behaving that furnish the most fruitful basis for judging what his future adjustments are likely to be; while the results of the psychological tests disclose abilities and disabilities that, when properly interpreted by the well-trained interviewer in the light of all other information about the applicant, contribute an addition to employment technique that is invaluable. But neither by itself offers an adequate method for diagnosing potential work adjustments.

We have in the interviewing situation a problem to be attacked similar to that presented to the psychiatrist in diagnosing the factors underlying his patient's behavior disorder and making a prognosis of the future outcome

We have come to the conclusion that every phase of the study of a given case as it is carried out by the clinician can be utilized by the interviewer in determining the work adjustment possibilities of a given applicant.

Importance of Detailed Knowledge of the Job. In order that the interviewer may be able to predict with any degree of satisfaction the possible success or failure of a given applicant, he must be well acquainted with just the thing that the applicant is expected to do—the job and its environment. Not only is this true from the point of view of routine work and production records but from the viewpoint of the possible effect of the work on the individual employee.

If he is skilled in his technique of eliciting information as to the individual's personality, he will be none the less ineffective in selecting good material for particular jobs unless he has so complete a knowledge of the work that he can relate the personality factors brought out in the interview to the particular ones desirable or undesirable in the job in question. Even such seemingly like jobs as those included under the general head of clerical work present problems in individual fitness which the interviewer cannot meet unless he has at hand a thorough analysis of the job and has incorporated this into his employment technique. Not only do the details of the work vary, but the environment, the type of supervision, degree of concentration, amount of variation within the job itself, etc., all are different, sometimes even within a limited section.

A first hand acquaintance with a task through actually working at the job itself for a short period is desirable. Every effort should be made by the interviewer to analyze his own mental content, his feelings and attitude toward the job he is studying. He should seek to put himself in the place of a potential employee and introspect on his own reactions to the given work.

It is important that he make some judgments and secure some actual information bearing upon the type of people who do just this sort of work; what sort of equipment, from a physical and mental viewpoint, is needed; what sort of social status is the group drawn from; what ages, schooling, etc., seem pertinent to this type of work. The more he knows of the personalities that succeed and those that fail the more accurate will be his employment selection. As he comes in contact with the job, he will find that often other considerations than the actual work itself are determining factors in connection with the satisfaction of the employee and his or her ultimate status. Such matters as the personalities of those supervising and at the head of the department; the ideals and standards of the department; whether loafing on the job and mediocre results are tolerated, or whether an overamount of pressure in order to meet the demands of exacting production records is the rule; whether the department as a whole is well tuned up to that sort of work achievement that gets the best out of the individual employee at the same time that the greatest amount of individual contentment and average normal health is maintained among the employees.

For the interviewer to know all of these facts means constant contact through personal follow-up actually on the job. None of these data are of sufficiently static quality to be acquired at one blow, and then retained for permanent use. Only the merest outline in the way of job specifications

and analysis can be given him through the ordinary write-up of the work. The many changing relationships that have to do with the success or failure of the people who do the work can only be fully grasped through his own intimate personal contact with those who are daily on the job.

As a reminder and special guide, there should be available carefully prepared job descriptions, job analysis, job and personnel specifications. This material is likely to change from time to time, but it will be a helpful aid in keeping before him at all times the essential facts to be considered in connection with any given job.

Methods Employed in Conducting the Interview. The employment interview may be conducted under the following main headings: (A) personal history, (B) personality study, (C) home problems.

Personal History. The personal history may for practical purposes be considered under the following headings: (1) developmental history, (2) health history, (3) educational history, (4) work history. (The interviewer should probably start the interview with the work history.)

The *developmental history* has to do largely with an inquiry into the important facts relating to the normal physical and mental development of the individual, and for practical purposes is of little use in connection with the employment technique. It is a fundamental field for investigation in the clinical study of an individual as a patient, but in connection with the employment interview, the information gathered will prove difficult to evaluate. So that this phase of the study may be practically ignored.

The *health history* is a most important, and in fact an essential field for investigation, not only from the point of view of actual past or present physical conditions that may seriously affect the applicant's chances for success at work, but as throwing light on mental conditions and personality disorders that so commonly reflect themselves in bodily complaints and influence the employee's work value. An acquaintance with psychopathology will give the interviewer an insight into the meaning of many of these supposed physical symptoms and their significance in the individual's work adaptation—how and why certain people become sick and later accomplish a neurotic adaptation toward life. These issues will be discussed in more or less detail under the heading of personality study.

It is advisable to inquire into the past health history with special emphasis upon accidents, operations, convulsive seizures, the ordinary physical defects and disorders and serious or prolonged and debilitating illnesses. Recent changes in the applicant's health and his present physical conditions should be carefully questioned. These conditions often show themselves in changes in appetite, digestion, sleep, and his feelings of general well-being. Fatigue, headaches, dizziness, constipation, eye strain, indigestion, insomnia, menstrual difficulties, and the like are brought out in the interview and these often are of considerable importance in enabling the interviewer to make judgments as to the future work value of the applicant.

Frequently the medical examiners will accept as a fair risk individuals whom the well-trained interviewer will turn down as being unprofitable material for the reason he has long since learned that the issues which actually lower the worker's efficiency and production value are not so much due to recogniz-

able physical diseases and defects, as to the mental attitude with which the individual deals with his personal and other problems; not so much what is actually the matter with him as what he thinks, or wishes, or feels to be the matter with him.

He will bear in mind, however, that he is to leave to the medical examiner the acceptance or rejection of new employees when physical conditions affecting work value are in question. A health record of the applicant will, however, often throw light upon important matters affecting physical endurance, ability to work under steady pressure, to tolerate standing jobs, lifting jobs, long hours, extremes of heat and cold, exposure, etc., and should be thoughtfully taken by the interviewer as a part of his study of the individual applicant.

Educational History. The school career and the educational background secured by an applicant for employment may throw light on many issues that determine the choice of work, and sometimes success or failure in certain jobs; it may even throw light upon the intelligence development and the drives in his personality, such as ambition, vocational interests, etc.

Such a history, when properly taken, gives a picture of the opportunities the individual has had for equipping himself, and the use he has made of these opportunities. While the practical purposes of the inquiry must be definitely limited to essential points of which the interviewer can make immediate use, still in some cases a more extended investigation is profitable. Our object here is to call attention to those essential facts that must be obtained in any given case, such as:

1. Grade reached in school.
2. Age at leaving school.
3. Going to school at present?
4. If so, nature of studies being undertaken.
5. Special vocational training.
6. Work experience that provides specialized training.
7. Future educational plans.

The *work history* should start off with an inquiry into the individual's first regular job, its nature, as well as the type of concern in which the applicant was employed, the salary he received, the duration of his employment, the reason for his leaving, the length of interval before the next job, its nature, the type of business with which it was associated, the salary received, his attitude towards the work and the people, the duration of that employment, his reasons for leaving, the length of the next interval of unemployment, and so on, and on up to his present position, or last work at which he was employed. These details should be taken personally and not necessarily secured on the employment blank.

A carefully gotten work career throws a striking light upon the personality of the applicant, and data secured from it can be included under your estimate of the personality characteristics of the individual. It not only indicates whether or not there has been a purpose and goal to which the individual has been striving, but also what degree of success or failure he has met. The work career brings out specialized interests and experiences, and becomes,

when properly taken, a valuable index to the future work ability and adjustment of the applicant.

It is important that this phase of the interview be thoroughly conducted in a scientific spirit and not hastily brushed over; for no better source is available in the entire investigation for forming safe judgments concerning the individual's work adaptability.

This, the work inquiry, places the applicant at ease, inasmuch as it enables him to talk about himself and about things with which he is entirely familiar and in which he is usually interested. It is a good idea to start the interview at this point of the history.

Personality Study. The most important phase of the interview is the inquiry directly relating to the personality make-up of the applicant.

Our first approach to this problem will be to select certain fundamental aspects of human behavior and describe them with a view to the evaluation of "the whole individual." Many of the characteristic reactions are evoked only through the social environment, and the interviewer will have to depend upon the personal history, or the individual's own account of how he has met certain given situations, in order to judge the typical reactions, trends, or drives, within the individual. Often his method of securing adequate data to make such judgements will have to be indirect and very general in approach. This account, from the individual, of his attitude toward important problems and his ways of behaving to fundamental situations must not be confused with the many forms on the market for making self-estimates of one's ability and character. These self-ratings have proved unreliable both in experiment and in daily life. But the personal history, when taken directly by the thoroughly trained investigator, brings to the surface motives, attitudes, and characteristic traits of the personality that undeniably act as the driving forces in behavior.

The value of such data will, however, depend upon the interviewer's powers of observation and his facility at analysis and interpretation. This will show itself in his evaluation of physical appearance, significant attitudes, bodily movements, mannerisms, facial expressions, voice moods, definite drives, mental patterns, and the general symptomology presented in each case. Of course, the better acquainted he is with the clinical case method of study, the greater his diagnostic ability is likely to be.

He should have read Mr. Shand's book on the "Foundations of Character"; Dr. McDougall's book on "Social Psychology," also "Abnormal Psychology," by the same author; "Social Psychology," by Allport; "The Trait Book," by C. B. Davenport; the "Foundations of Personality," by Meyerson; White's "Outline of Psychiatry," also his "Foundations of Psychiatry"; and he should be acquainted with the mental hygiene literature gotten out by the National Committee for Mental Hygiene, 370 Seventh Avenue, New York City.

That type of outline which brings into play those characteristics which most readily may be investigated, will be most serviceable to the interviewer. The following traits, or main divisions of the personality are suggested:

1. Intellectual activities.
2. Motor characteristics.

3. Temperament.
4. Self-expression.
5. Sociability.

Intelligence. We are all familiar with individuals of superior intelligence who get low grades in school, or out in life fail to make use of their intelligence; also we know the individual of dull intelligence but with a determined drive, with ambition and industry, who gets high marks in school and makes a reasonable success in life.

In other words, possession of intelligence, of quickness of perception, cleverness of learning, good memory, and adequate reasoning ability does not imply successful adjustment or solution of life problems. There are other factors, namely, habitual trends of effort in the direction of accomplishment, or what may be termed the "drive," of the personality, that have more to do with determining success or failure than the degree of intellectual development.

General intelligence may be considered to be that ability or special trait of the personality, by reason of which the individual learns and comes into possession of knowledge of his environment. It may be termed the individual's "problem solving ability," or "reasoning capacity." Like the physical growth of the individual, the intellect should progress from year to year in its development.

There are certain practical questions relating to the intelligence, that the interviewer should have in mind when he investigates this aspect of the applicant's history:

- A. Is the applicant's education commensurate with his opportunity for it?
- B. Is he alert?
- C. Has he seemed to learn from experience or is he naive and gullible and does he repeat the same mistake over and over?
- D. Is he attentive, and does he seem to fix and hold his attention well?
- E. Does he give a consistent, intelligent, well-related story?
- F. Does he seem distractible?
- G. How suggestible is he?
- H. Has he any special aptitudes, or special interests?
- I. Is his memory good?
- J. Does he show good common sense?

Motor Characteristics. We might include under this category such traits as overactivity, underactivity, speed, impulsiveness, inhibition, tenacity, skill, etc. We are all of us acquainted with the overhasty, impulsive, restless, talkative, bustling type of individual, who rushes through his duties at great speed and probably completes no task thoroughly. Then there is the slow, underactive, static individual, who cannot keep up with the pace set by the normal worker. There are all types of modifications of these characteristics, but they ordinarily are constitutional in origin and indicate the motor set or pattern in any given case. Undoubtedly well-controlled and suitably directed movements, free from haste and spurts of activity, keyed to a healthy normal rate of speed, in the long run secure the best work results.

One important thing to recognize is that the overactive individual may show powerful impulses which drive him to action in order that he may give the appearance—either to himself or others—of being in great haste and having much to do. Or, he may show overactivity, due to excessive energy output, free from the normal inhibitions that commonly are built up in the average person to permit of the wisest choice among a group of possible lines of action; while the underactive personalities may exhibit inertia, due to limited energy output or to powerful repressions and restraining inhibitions.

Questions in the mind of the interviewer might be as follows:

- A. Does the applicant display tension or "push" in his activity?
- B. Is he restless or overactive?
- C. Does he seem inert?
- D. Does he seem static?
- E. Is he overtalkative or undertalkative?
- F. Would you judge his activity to be persistent and steady? Or capricious?
- G. Does his life history indicate that he has or has not finished undertakings?
- H. Does he seem sluggish or lazy? Does he slouch as he walks or sits?
- I. Would you judge him easily fatigued?
- J. Do you think that he could be speeded up easily? Or easily slowed down?
- K. Do his movements seem well coordinated?
- L. Are his posture and gait good?
- M. Does he appear energetic?
- N. Would you judge him to be tenacious and persistent in the face of obstacles and discomfort?

Temperament. Feeling and emotion are exceedingly important constituents of personality on the subjective side; as they influence the mood of the individual they become one of the most important subjective elements in his actual behavior. The emotional attitude or set colors the outlook and modifies the individual's adjustment possibilities far more frequently, and more seriously, than is ordinarily believed to be the case. Their dynamic value in the personality is seen in the mechanism of reinforcement and repression; in pushing the individual into overt behavior, or in inhibiting tendencies to act along certain lines.

The emotional attitude, the emotional stability, and the degree of control over the feeling and emotional aspects of our lives become among the really vital issues that influence job adjustment in any given case.

It is wise then for the interviewer to acquaint himself with the psychology and pathology of the emotions, so that he may apply this information in his analysis of each applicant for a job. He can well emphasize this phase of his investigation, particularly in connection with his follow-up work on the job, where he will find that many of his impressions that seemed little more than hunches have turned out to be dynamic factors, which he now can investigate in their definite relationship to the behavior of a given personality to work.

What we call temperament may be understood as the characteristic emotional level of the individual, such as the choleric type, the phlegmatic

type, the sanguine type, etc. The leading question concerning any given individual may profitably be—what part do emotions play in his daily life? Some people have a characteristic mood that is very easily discerned. They are of a gloomy, sullen, sour temperament and disposition; or they are cheerful, optimistic, and hopeful; suspicious, timid, embarrassed, oversensitive, self-deprecatory; or pompous, cynical, snobbish, or irate. These moods and emotional attitudes greatly influence one's relationship with others and are very important factors underlying work failure, or work success.

Something may be done to change the trend of moods, through contact with the individual, through an effort to understand the origin and development of emotional sets and attitudes and through seeking to give the individual a different viewpoint and providing interests of a healthy and normal type. The results, of course, will depend on the intelligence and the cooperation of the employee, and the amount of time that can be spent in this direction.

The interviewer is to bear in mind that the significant implications in this whole situation have to do with avoiding the selection of applicants who exhibit too marked extremes of temperament and mood—the depressed, melancholic, sullen, irritable, and grouchy person, as well as the extremely cheerful, overoptimistic, exaggeratingly enthusiastic types. These extreme types are unusual and almost invariably make poor personnel risks. Everyone, of course, presents mild emotional attitudes accompanying his thoughts and actions, and when these emotional attitudes become fixed and permanent, they result in what we call traits of character.

Special Characteristics or Traits of Self-expression. *Extroversion, Introversion.* We have here reference to the tendency in individuals to make external or internal adjustments. The extremely introverted individual obtains his satisfactions within a world of his own making. Adjustments to reality of an external nature are interfered with by emotional attitudes and trends within the individual that block effective overt behavior. These individuals do a lot of daydreaming as well as night dreaming, where they are able to bring to fulfillment their repressed wishes, or to secure an adjustment that is satisfactory to them. The consequence is that sooner or later in many cases there is actual severing of a proper relation with reality. When the condition is markedly pathological, we have the beginning of a well-known mental disease—*dementia praecox*. However, many introverts are effective, brilliant people, who are able to handle their personality defects through compensations that enable them to make satisfactory life adjustments.

In introverts, real conditions are distorted in such a way as to satisfy the wishes, cravings, or viewpoints of the individual; an unreal and unnatural set of values is constructed out of life to suit themselves. There is an intense personalizing of all events and activities with which they come in contact and they develop what we call "ideas of reference," in which nearly everything that is said or done by others may have a personal bearing. On this as a background they easily build up persecutory delusions. It is easy to see how such individuals, unless they are particularly capable and succeed in making satisfactory adjustments in life through the possession of special abilities, tend to avoid and run away from the difficulties of a dull, prosaic,

uninteresting reality, or the routine of daily work, through the development of imaginary achievements and satisfactions. Marked introverts, unless they have secured some compensations through specialized abilities, had better not be employed as a general thing, though in some jobs such as "marking" they may show good production. Of course we know that many of our most skilled mechanics, best laboratory workers, and finest scholars are marked introverts. But here we have compensating factors of great saving value.

Extroversion does not present as clear cut a personality type as *introversion*. The extrovert lacks the symptoms of repression, oversensitiveness, unreality, protracted daydreaming, etc., exhibited by the introvert and represents more the normal, well-balanced, well-integrated personality. He makes contacts with people quickly and does not set up defensive attitudes nor respond with unintelligible bursts of emotion or inhibitions.

Both of these conditions, however, are subject to great modifications, and changes may be noted, through environmental influence, in the tendency to *introversion* or *extroversion*, particularly when one's circumstances change rapidly. Success, prosperity, and personal satisfaction tend to make the introvert more extroverted; while failure, disappointment, and chagrin produce in extroverts inferiorities and shut-in tendencies, sensitiveness, and defensive mechanisms. Extroverts make the best salespeople. Our own figures show that more than three-fourths of the good salespeople in Macy's store are readily classifiable as extroverts, while more than half of the poor salespeople are easily diagnosed as introverts.

Introverts who possess good clerical or mechanical ability, and do not suffer from very serious personal or home problems, may succeed well along clerical or mechanical or allied lines. In many of the non-sales groups we may well place carefully selected applicants with introverted trends if they do not show serious disorders of the personality.

Much may be said of the therapeutic effects of certain jobs in developing extroverted tendencies in introverts and thus adjusting them to reality. Cases could be given here to illustrate the results of our work in this direction.

We could continue along these lines and go on further into a detailed discussion of other personality classifications or characteristics of makeup, such as dominant personalities, submissive personalities, expansive types, reclusive types, emotional types, egocentric types, paranoid types, and inadequate types. Each one of these classifications includes a symptom complex that is peculiarly distinctive, and has certain bearings upon the clinical inquiry for employment.

The paranoid individual, for instance, with his suspicious nature, will not do well in team work, and no matter how much special ability he possesses is always liable to be a source of irritation and dissatisfaction in a closely organized group.

The egocentric personality, if marked, is very likely to be a "grabber," an individualist and a disciplinary problem.

The reclusive personality will certainly not do well in any type of work requiring contact with people; he avoids people, is shut-in, self-centered, and keeps his light hidden under a bushel.

The emotional personality is handicapped at work through his undue excitability or his marked moodiness trend.

The inadequate personality is often lazy, indolent, lacking in energy and "pep," and no matter whether he has good abilities or not, his production is always likely to be low.

It is well for the interviewer to be acquainted with the traits and characteristics comprising these classifications and he should read general psychiatric literature, so that he may become acquainted with the significant implications involved.

Of course, it is clear that we are referring to marked deviations from the average normal personality make-up when we classify a personality as being definitely "egocentric" or "paranoid" or "introverted," and the like. It is these extreme types which are in mind when we warn the interviewer against the problems they create.

Nervous and Mental Disorders. We have outlined, in our personality study, the need of evaluating the intelligence, the temperament and the volition, or motor characteristics, or will power of the applicant. We have also mentioned the desirability of considering the special traits of character that make for certain personality patterns, or types. We will now discuss briefly some pathological conditions that affect the personality and influence the applicant's success at work. It is not intended to cover all of the various forms of nervous and mental disorders, but simply some of the more common conditions with which the interviewer will come in contact.

Chronic Alcoholism. Suffused eyes, prominent superficial blood vessels of nose and cheek; flabby, bloated face; reddened aspect of the face, tremors of the fingers and of the tongue, tremulous hand-writing, etc.

Drug Addiction. Peculiar pallor of the skin; in opium users minutely contracted pupils, while in cocaine users widely dilated pupils.

Dementia Praecox. Indifference, withdrawal from reality, ideas of reference, and at times of persecution; inaccessibility, peculiar emotional flatness, eccentric posture and gait, an apparent gap between feeling and doing. The individual appears detached, odd, eccentric. There is often a lack of connectedness in conversation, though not always. Past history (school and work) and personal career will usually show erratic and irrational conduct. Of course, the more marked cases will complain of their thoughts being controlled by others; have marked delusions of persecution, hallucinations of hearing, and bodily hallucinations, frequently of sexual or electrical character; will exhibit meaningless smiles, and most inappropriate emotional reactions. Of course, all such cases need clinical or hospital care.

Manic Depressive Personalities. Mild depressions, (with or without feelings of inadequacy), fatiguability, talkativeness, marked overactivity, periods of exhilaration and expansiveness, marked restlessness, difficulty in holding attention on one task, etc. These individuals have periods of moodiness, "blues," inactivity and low work production, alternating with periods of great activity, restlessness, exhilaration, etc. They get "knocked out" by minor illnesses, have to do a great deal of resting up, need frequent vacations, etc. They often have good intelligence, and during their well periods may be dynamic, productive employees.

Psychopathic Personalities. There is a large group of individuals who cannot be classified as insane nor as feeble-minded, but who, nevertheless, are

incapable of behaving in a normal and acceptable way in the average environment. They usually have average or superior intelligence, and frequently have good ability, but they suffer from disorders of their personality that so seriously handicap their special talents as often to unfit them for much usefulness in society. They form the large body of the so-called "criminal class." They constitute the vagrant, the tramp, the unemployable group, and the periodic drunks. Their emotions are usually distorted and their life career is more nearly patterned on an instinctive basis than that of the ordinarily socialized adult.

The above classifications of paranoid personality, emotional personality, inadequate personality, egocentric personality, when exhibited in a marked degree, constitute what is called the psychopathic personality. In these cases there is a constitutional basis, ordinarily, for the mental life they exhibit. This may be either hereditary or acquired in early childhood. They are frequently very suave and make a good first impression.

The interviewer will notice in their work career and personal history the marked instability characteristic of these cases. Their employment is a risk, but if hired they require the closest, most painstaking and understanding follow-up.

Psychoneuroses. Hysteria, neurasthenia, psychasthenia, anxiety neuroses, and such states are functional rather than organic conditions that often have no objective signs and may thus escape notice. These individuals commonly suffer from hypochondriacal complaints, undue fatigability, marked "nervousness," inability to concentrate attention for any length of time, irritable weakness, pessimistic moods; they pay a great deal of attention to the function of their bodily organs, they have periods characterized by heart palpitation, difficulty in breathing, profuse perspiration, trembling, shaking, disturbances in appetite, dizziness, diarrhea, etc. Of course, not all of these symptoms are presented in any one patient, but the conditions from which these individuals suffer are mental in origin. They often can be adjusted under proper treatment, and are found frequently in perfectly good employees. But unless suitable treatment is instituted, these people sooner or later become serious personnel risks, and the disorders from which they suffer definitely lower their production ability. *Rest, sympathy, and medical treatment at the level of their physical complaints is just the thing they do not need.* These are all adjustment problems that must be dealt with as psychiatric cases. They had better not be employed to begin with, but when found among regular employees they should at once be referred to the psychiatrist.

Epilepsy. Epileptics are not easy to discern at the time of the interview. They frequently deny seizures altogether and in the history they often present nothing more than severe nightmares, dizzy spells, severe headaches, spells of weakness, etc. Their personalities are usually distinctly abnormal; they have violent and irritable spells, often over the most trivial causes. They have marked likes and dislikes, peculiar defects in memory, poor retention, and their behavior is unpredictable. They often have very difficult personalities and are egocentric in make-up. Their convulsive seizures render them a poor personnel risk.

Feeble-mindedness or Mental Deficiency. This condition is due to an arrest in mental development. The mind fails to grow commensurately with the body and there is a disproportion in the actual age and the mental age of the individual. They have the judgment, reasoning ability, learning capacity and understanding of children under eleven years of age. As a consequence they are unable to compete in life with the average normal man or woman. These mental defectives are best discovered through psychological

tests. They are often good workers and may make the most satisfactory employees if free from handicapping personality disorders and placed in a type of work specially suited to their limitations.

Individuals securing an intelligence quotient between 60 and 70 show borderline defective intelligence, while those under 60 have defective intelligence. Of course, this presupposes that the question of language difficulties in the case of the foreign born, and pathological conditions that produce mental deterioration or confusion or great distractability, etc., have been duly considered in drawing conclusions from the results of the psychological tests.

Need for Some Technical Knowledge on the Part of the Interviewer. All the above mental conditions are just mentioned in passing in the most summary fashion. The interviewer should carefully study such textbooks as White's "Outlines of Psychiatry," Henry's "Essentials of Psychiatry," White's "Foundations of Psychiatry," and other such psychiatric literature in order to get a more technical acquaintance with the symptomatology of nervous and mental conditions. No specifications or outline or guide can give him an adequate background for interpreting each case. This must be an outcome of his own growth, through reading, study and actual work.

Physical Condition. About 9 per cent of those examined physically for employment are rejected because of physical defects or disorders that make them unprofitable risks. Heart and blood vessel conditions lead the list, constituting about 26 per cent of rejections. Such conditions as diseased tonsils, hernia, very bad teeth, extremely defective vision or hearing, may cause rejection by the physical examiner. But there are a host of physical conditions that more or less modify the physical health or efficiency of the worker—nutritional disturbances, glandular disorders, flat feet, dysmenorrhea, kidney conditions, chronic rhinitis, sinus trouble, etc.

The common causes of illness, such as infections of the upper respiratory tract, indigestion, and functional disturbances of the nervous system, cannot be traced directly to defects that can be found by routine physical examinations.

Dr. Swan has shown, however:

... that a very definite relation exists between the physical condition of employees and absenteeism. Employees who need dental work, who have uncorrected errors of refraction, who are more than 15 per cent over or under weight, or who have some other defect that many people may consider unimportant, are sick more often, and therefore absent more than those who are in good physical condition.

Employees who have organic heart lesions, hernias, and serious defects are absent 42 per cent more than those in good physical condition. The relationship is largely indirect; the disability as a general rule not being the direct cause of the absence.

Suggested Outline for Personality Study. I. Facial Expression. Does the applicant look fearful, anxious, apprehensive, shy, timid, sad, gay, surly, hostile, suspicious, visionary, gullible, expressionless, intent, alert, eager, arrogant, cynical, fatigued, interested, indifferent, resistive, supercilious, etc.?

II. Movements. Are there movements of the head, of the face, of the body, of the hands, of the feet? Are there rhythmic quiverings of the mouth? Are there wrinklins of the forehead, peculiar facial expressions, peculiar

attitudes of the body, nervous twitchings of the hands, licking of the lips, biting of the nails, idling with pencils and paper, etc.

III. *General Observations.* Does the employee speak voluntarily to the interviewer of his own problems, interests, and ambitions? Does he talk freely and intelligently? Does he give a related story? Does he make a good first impression? Does he seem well-developed and well-nourished? Is his color good? Does he appear well-dressed and neat? Is he careful about his clothes? Does he make a good contact? Does he appear to be full of problems of an emotional nature? Does he seek a listener, and seem anxious to talk about his troubles? Does he appear self-centered? Does he crave sympathy, etc.?

IV. *Speech.* Is the voice well modulated, full, resonant, pleasing? Or is it pinched, small, strained? Or loud, harsh, irritating? Does he stammer, or slur words, or lisp, etc.?

V. *Mental Attitude toward Work.* Give details of the attitude shown by individual toward the jobs he has held in the past, and his reasons for leaving them; his eagerness to secure other work, how definitely decided he is on the present job under consideration; his attitude towards the nature of work it calls for; his vocational interests and work ambition, etc.

VI. *Mental Attitude toward Authority and Associates.* It is wise to make judgments of the applicant along these lines, inasmuch as the inability to take directions from those in charge, to work carefully under supervision, or to get along with one's associates is an important cause of resignations and lay-offs.

VII. *Mental Attitude toward Home Relationships.* Is there friction, worry, or difficulties of a psychological or financial nature at home? If so, how do they affect the individual, and his attitude towards them?

VIII. *Mental Attitude toward Himself and His Own Personal Make-up.* How does he feel about his own personal defects and disorders? Does he complain much? Does he overreact, taking the whole thing too seriously? Does he feel inferior, ashamed, shy, timid, or superior and well satisfied with himself, etc.? What is his attitude towards his own failures or achievements?

IX. *Psychoneurotic States.* Such people complain of undue fatigability or irritable weakness or inability to concentrate attention for a very long period of time, pessimistic moods, subjective disturbances of the nature of difficulty in breathing, profuse perspiration, trembling, shaking, disturbances in appetite, dizziness, diarrhea, etc. These cases pay more or less continuous attention to their bodily functions, their attitude being to no small extent fostered by the undue sympathy received, or by medical treatment at the physical level, which in many cases centers the patient's attention at his bodily functions.

X. *Psychotic States.*

XI. *Other Mental Conditions.* Peculiar ideas or feelings of uncertainty or doubts, memory defects and other undefinable miscellaneous conditions.

XII. *Recreation.*

XIII. *Summary of the personality traits or characteristics (having specifically in mind the qualities or traits suited to the job in question).*

Home Problems. It is important to know whether the individual lives at home or away from home; whether his family is partially dependent or totally dependent upon him. What is the nature of the home problems he has? One usually asks whether father or mother are living, or dead; in good health or poor health; divorced or separated, or living together; whether the father is employed, and if so, the nature of his employment. The same

for the mother. Number of brothers and sisters, their ages; number at work. Where the residence of family is, etc.

Is the applicant single or married? If married, how many children? What is the economic status? Are there home problems? If so, of what character?

It is obvious that difficulties in the home may influence seriously the mental life of the employee; bringing on depression or daydreaming; may affect his attendance or his production; may be the most important factor requiring him to stick at work, or the greatest cause of his resignation. A short outline of the home situation should be routinely taken.

Evaluation of the Psychological Study. From the point of view of measuring certain abilities involved in the performance of certain jobs, the psychological method of testing is in many respects superior to general observation, or to personal opinion, inasmuch as it is an objective, and thus a more accurate way of measuring behavior. It does not depend upon the subjective impressions of the examiner, which may vary from time to time in the same individual, and certainly will vary considerably with different examiners; also the results can be compared with those obtained in previous studies of the same individual, or of other individuals, and standards of achievement can be established.

Unfortunately, we cannot measure the total reactions and potentialities of the entire human personality, so that the method necessarily is limited in its value as a basis for prognosing the future adjustment of a given person. There are, however, some aspects of the total situation that are in a way measurable. What we popularly call general intelligence (or mental alertness), learning ability, speed, accuracy, motor dexterity, knowledge of arithmetic, etc., are subject to the experimental method of the laboratory, and the results achieved already in measuring these mental processes are usually quite superior to the generalizations of most examiners.

Consequently, psychological tests properly administered can become a tremendous aid to the well-trained interviewer, in helping him diagnose the abilities, the disabilities, and the adjustabilities of an applicant. They do not claim, however, more than they can actually accomplish. They can give an individual a score in motor dexterity, or in accuracy, or in speed of reaction, or in appropriateness of reaction, or in general intelligence, but these scores alone cannot tell whether an individual has it in him to make a good cashier, or a good marker, or a good clerical worker, or a good driver, etc. These are issues far more complex than the mere possession of abilities to perform the task required—issues that are only understood through a well-rounded, thoroughgoing clinical study of the total individual, the entire personality. This we have outlined in the foregoing pages.

It is through the utilization of the psychological test method as an adjunct to the interview that the applicant's potentialities can best be determined. But we will bear in mind that a high score in intelligence does not necessarily mean success at work, nor a low score in intelligence signify failure. We will want to know about the "drive" within the individual, his real interest in the proposed job, the make-up of his personality and its fitness for the work to be done, the physical health, the mental attitude, the work experience,

etc., in every given case. The individual may be rated "good" in all special ability tests, and make a tremendous failure on the job because of the personality trends and difficulties that handicap him. He may be rated only "fair" in certain ability tests, and yet have the tenacity, industry, and ambition that ultimately win.

In our own work, psychological tests play a definite and sometimes important part. They are used as clinical aids to bring out certain reactions and tendencies that our job analysis and job specification study have indicated to be factors of considerable importance in performing the task. But we do not ask, or expect more of them than they are intended to give.

It can be seen from our previous remarks that there can be no greater fallacy than to put the interview on one side, and the laboratory method of measurement on the other, as though they are to be considered opposing methods of approach to the evaluation of the same factors in the mental and physical make-up of the applicant. They must be viewed as two different aspects of the same examination—the qualitative and quantitative viewpoints. Certain phases of the study can be gotten best through a qualitative or clinical inquiry; while other aspects may be measured quantitatively. They go together to make a whole, and the employment technique, as we see it, is not complete without both.

Our own procedure at Macy's provides for giving to each job certain criteria and setting certain standards in the way of intelligence or accuracy, knowledge of arithmetic, speed, etc., which we expect to be met by applicants seeking employment. Our job specifications, which are in the hands of each interviewer, indicate the ratings set for each one of these items.

The following criteria for cashiers will illustrate this point:

Cashiers' Criteria

1. **Ages.** From seventeen to twenty-five are the best, preferably between twenty and twenty-five, except part-time married women, who may be between twenty-five and thirty. Young married women do better in part-time work than single girls.

2. **Schooling.** Grammar-school graduates are required. The farther up or down the scale, the greater frequency of problems.

3. **Personality.** Good attitude is essential. Those suffering from serious conflicts, the so-called "nervous types"; those with emotional maladjustments, wrong mental attitudes, and seriously faulty ways of meeting their problems; those who daydream or indulge unduly in mental reverie, particularly of a pessimistic nature, are liable to make errors and be slow in their transactions as cashiers. The well-integrated, well-focused, objective types who are alert, vigorous, and free from too much introspection; those who can develop a high degree of organic tension and maintain it constantly during work make the best cashiers.

4. **Physical Conditions.** Vigorous, healthy girls, neither too fat nor too thin, free from any debilitating conditions or tendency to fatigue, with good muscular development, make the best physical types. The condition of the eyes as to vision and muscular balance is essential to consider. Also any condition of hands, wrists or arms, that may handicap or limit freedom of movement and motor dexterity, must be looked into.

5. **Home Conditions.** Serious home conditions, particularly serious illness or domestic difficulties other than financial, are apt to produce what is called daydreaming and error-making.

6. Intelligence. Intelligence quotients between 90 and 110 produce the largest proportion of satisfactory cashiers. I should not take any with an I. Q. under 80 unless the job tests and the rest of the study indicate well-developed specialized ability, and I would scrutinize carefully those over 110, as the latter are apt to become dissatisfied with the opportunities for advancement. Still, the social status is an important consideration, as many bright girls come from homes where a cashiering job would be quite an acceptable social achievement.

7. Speed. Those marked "poor" in speed should always be turned down, no matter what the other findings are. Either "good" or "fair" speed may be acceptable.

8. Accuracy. Do not accept any one marked "poor" or even "fair" in accuracy. Demand "good" for a rating. Otherwise, error-makers will get in.

9. Learning. Either "good" or "fair" is acceptable.

10. Arithmetic. Either "good" or "fair" is acceptable. Turn down those marked "poor."

11. Motor Dexterity. Preferably those rated "good."

Of course, the final interpretation of all findings becomes an individual matter, for which fixed and written standards cannot be set, and numerical ratings of the entire study not adaptable.

The above is the kind of an outline that the interviewer is to have in mind as a mold into which she seeks to fit the applicant for the job of cashier. We have developed the same sort of standards and specifications for other jobs within the store.

Summing up the Data as a Basis for Diagnosis. It may be seen from the foregoing outline of methods which should be employed in conducting the examination of an applicant for a job, that a fairly careful and well-thought-out technique is desirable, if we are going to evaluate the really important factors involved in the individual's success as an employee.

The interviewer's genius in selecting the right sort of people will frankly depend upon his ability to sense the important issues, as he brings together the various facts gleaned from the personal history, the personality study, the home inquiry, and the psychological examination, into his brief and clear summary of the case. Sound judgments and accurate predictions cannot be accomplished in the twinkling of an eye. A routine systematic procedure that involves a critical inquiry into every phase of the whole examination, and a thoughtful balancing of every factor that goes to make up the final picture of the total individual, develops in the interviewer what may be called a diagnostic acumen.

He is concerned fundamentally with making a prognosis in the case of each applicant. His own mental attitude is quite important, and essentially different from that which he assumes to the individual he has already employed and is following up in his effort to adjust to the job. In the former instance, he must remove himself from any emotional attachment that may interfere with his judgment; while in the latter instance, he may well allow sympathy and personal interest to play a part, as they sometimes will drive him to harder work, in preventing or overcoming maladjustments that lead to resignations or lay-off.

Of course, his ability to group together all the important facts or symptoms and make a diagnosis will depend upon his knowledge of human behavior in its abnormal, as well as normal, aspects and his experience in applying such information in connection with actual work situations. In the final analysis, he shows his genius in the ability demonstrated in summing up and evaluating the data he has obtained.

Follow-up on New Employees. The follow-up and adjustment end of employment work becomes, to our mind, probably the most fundamental phase of the interviewer's work. The lack of a routine, systematic, and well-planned follow-up program is, in our opinion, one of the greatest shortcomings in present day employment technique.

Securing people who are potentially "fairly good" is not a seriously difficult task in employment technique. But developing and adjusting them, and finally retaining them, is another matter. Here is a responsibility that is distinctly a concern of the Employment Department.

Many issues that bring about work and personality maladjustments are already present, and must necessarily be present at the time of hiring. For we have made quite clear the impossibility of our ever being able to secure what may be classed as absolutely good material for every job; there is not enough to go around. The great majority of our new employees will in the final analysis have to be rated as only fair material; a small proportion will be distinctly good high-grade stuff. Our interviewers will recognize and fully assess these matters, and in their close follow-up will bear in mind the adaptabilities and disabilities of each individual, and the potentialities for failure that may lurk in many a fairly promising employee. They will understand these matters and seek to deal adequately and effectively with each case, in order to forestall resignations, drops, and lay-offs. For this is the road to the reduction of turnover—not through dependence alone upon correct selection at the time of employment. This is a prevention program, in which the reduction of work failures is largely brought about through an intensive follow-up and adjustment régime, immediately following upon employment and placement. This is a program that requires a change of emphasis from a hypothetically perfect hiring technique in selecting just exactly the right person for each job, into a developing and adjusting technique of improving human individuals and making them of greater value to themselves, their employers, and the community in which they live. This is much cheaper and certainly more profitable from a human viewpoint than the simple hiring and firing policy so commonly in use.

Upon whose shoulders shall fall the responsibility for this follow-up program? It is our belief that the interviewer, who has originally diagnosed the work potentialities in each case, who has gone over every phase of the applicant's qualifications and disqualifications for the job in question, and who understands the peculiar personnel problems presented by each personality he has employed, is the one person best equipped to follow up each new employee intelligently with a view to work adjustment. His knowledge, secured at the time of employment relating to individual and personal factors involved in work adjustment that may lead to success or

failure, will enable him to anticipate maladjustments, to detect early difficulties and often prevent actual separation of the individual from the job.

It must not be thought, however, that the interviewer will have either the time or the equipment to make an adequate psychiatric analysis and undertake anything like satisfactory treatment work on problem cases, particularly those of the more complex types.

People will become mentally ill under stressful situations despite the fact that they have in the past been usually well adjusted. Personality difficulties, loss of interest (due to serious mental conflicts), anxiety states, irrational reveries, etc., will develop in people who previously had never presented such problems.

The value of our technique, here discussed, is not in its provision for the interviewer to handle these more serious disorders of the personality and endeavor to treat them, or just to recognize them and have the individuals laid off as is now so commonly done, but to see the significant treatment possibilities in each case, to detect such types of cases throughout the organization. Much in the way of actual psychiatric treatment and prevention may be accomplished by early reference to the psychiatrist for well-rounded study and treatment.

All of our work proves that, through catching these maladjustments early in the employee's store career, and setting in motion the type of adjustment machinery with which we are now equipped, we will cut down enormously on our turnover problems, and will raise the production capacity of otherwise potentially problem cases.

It is important that we get a clear understanding of the real values that are to ensue from a properly organized follow-up system. These values are not to be seen alone in the adjustment of the new employee, for the interviewer himself becomes the greatest beneficiary. It becomes possible now for the first time to see his diagnostic ability directly put into practice. For now he is able to witness the results of his initial judgments and secure a self-criticism on his diagnostic technique.

There can be no growth in diagnosing the work adjustment and possibilities of applicants, unless the diagnostician has a chance to check up on his errors and mistakes, and unless he is able to secure a continually better insight into the problems furnished by the job environments for which he is employing. This self-criticism and technique analysis, plus the additional information about the department and its needs, will always furnish the interviewer a fresh and growing approach to his problem, and tend to make his work more professional.

Record Keeping. Good records must become the heart of our case work. There is no real growth without orderly, systematic, and well-kept records on each and every case. That the interviewer should have some well-planned method of recording certain detailed information about each individual he employs—what are the outstanding problems and what happens to them—if he is really to do effective work is simply to elaborate the obvious.

It is desirable that the method adopted be as simple and as free from unnecessary details as possible. It is out of the question to go into the case from the same thoroughgoing angle that the psychiatrist has to employ

in unraveling problem cases and thus to keep a detailed case record on each case for purposes of research work into the causes of maladjustments.

The nature of the record employed by the interviewer is to be thought of more as a simple card on which certain essential data that will guide him concerning his case will be placed.

When an applicant is employed, the findings in the particular case, including the psychological data and all of the essential facts obtained in the clinical interview, should be recorded in a few words on the "record card" that is to be kept by the interviewer on his own desk. Also he should record on this card all of his follow-up data on the individual. He should also keep a loose-leaf notebook in which he will write in more detail the information he secures in his follow-up work on the case, so as to guide him during his period of contact with the new employee. This information, naturally, cannot be placed on the record card, except in a most symbolic or abbreviated form.

On the first line of the card is placed the new employee's name, department disk, and date employed. Then on the left-hand side of the card the psychological and clinical interview data, such as I. Q., speed, accuracy, arithmetic, motor dexterity, filing, and whatever tests may be used for the particular job in question; then the age, schooling, work, personality, home, and other information, as well as outstanding health problems or physical handicaps, etc.

The follow-up data is placed on the back of the card. This should include brief mention of the dates of his own follow-up together with reference to any very outstanding information. It is important that he secure information from the divisional teacher in the training department as to the results of training, and in fact start his follow-up with this information which he secures from the training department.

The follow-up should be regular and systematic and should continue uninterruptedly until the interviewer is sure of the adjustment of his case.

A suggested arrangement for a record card is given on page 1099.

Periodic Analysis of Work. At least once every six months there should be a careful stock taking, a statistical evaluation of the work done, a rigid scrutiny of the results achieved.

Every single case should be gone into and the final status determined. It should be the purpose of the interviewer to analyze thoughtfully the material in terms of each individual employed, as well as the entire group from a statistical viewpoint. He would then be able to understand clearly and interpret significant trends, bring out the weaknesses in his methods, and profit by the mistakes he has made.

There is no other means of growth more satisfactory than that obtained through a periodic analysis of one's own work.

Conclusions. We have in the preceding pages given a very brief outline of a guide for the employment interviewer, based upon well-tried methods of studying human behavior.

We have suggested an employment procedure that is fundamentally clinical in nature and that seeks through an application of medical, psychological, psychiatric, and social technique, to discover and evaluate the essential factors underlying the individual's life adjustments, to prognose

his work potentialities and to improve his ways of meeting job and other life situations.

Name		Nationality	Date employed	Salary	Department
Date of birth	Height	Education			
Work history			Appearance		
Health problems					
Home and living conditions		Job interest	Tests		
		Rating G F P <input type="checkbox"/> <input type="checkbox"/> <input type="checkbox"/>			
Personality: Alert. Responsive. Convincing. Aggressive. Self-expressive.		Self-confident. Self-conscious. Nervous. Contacts. Stability. Reality.		Insight. Integration. Ambition. Poise. Patience. Attitude.	

It is out of the question to hope that in any mere brief discussion of this nature we can do more than call attention to fields of knowledge that should be carefully investigated by the employment interviewer in his search for information and training. He should read assiduously and study thoroughly the psychiatric literature. He should constantly grow through the close check-up and evaluation of his own work.

It is not to be expected that he will come into the possession of wisdom any differently from the slow and laborious methods pursued by all students who have to practice their art in order profitably to learn.

ETHICS AND METHODS IN HANDLING REFERENCES

By EARL B. MORGAN, *Consulting Engineer*

Definition. An employment reference is a statement of facts given upon request by a previous employer and should be based on the employment record of the subject, covering such items as period of service, occupation, wage, reason for leaving, rating on workmanship, attendance, and conduct.

It may not include all these items, but it should if they are all a matter of record, except possibly the wage when it is against the employer's policy to disclose it. It should not, however, include and should not be expected to include a forecast or prophecy as to how a subject's character and workmanship will fit a given set of requirements generally unknown to the informant. It should simply be a rating of past performance.

A personal reference is an opinion given upon request by a person named by the subject as being qualified to give it, covering character, integrity, general standing in the community, and should be based on either social or business acquaintance, or both.

These references should, if possible, be followed up before the applicant is engaged so that the information obtained can serve as one of the factors entering into the determination of the applicant's fitness for the position. This is not always possible with lower rank employees, especially when the labor market is tight and competition is keen. Such applicants will not wait until their references are checked; the only way to handle them is to maintain a waiting list, if the supply permits, and look them up as they are placed on the list. Otherwise, they must be employed relying upon judgment based on the information obtained through the interview, and then follow up the references as a check.

Form of Request. It is a common practice of employers to request an employment reference by sending a printed form drawn up in questionnaire style. Such practice, no doubt, effects a saving in the office routine of the inquirer, but it presents practical difficulties for the employer to whom it is directed. First, if the answers to the questions are typed, it is difficult to register to the spacing provided on the form; in fact, a typist can write a regular letter giving the desired information with less inconvenience. Second, if the form is used in answering the informant has no record for his files.

Those who use a printed or prepared form can prevent the first difficulty by providing blank space, say at the bottom, where a statement can be either typed or written in longhand. Obviously, the employer who wishes to keep a record always has the opportunity to do so by answering the request with a letter and retaining a copy, or making a carbon of the memorandum which is typed on the form.

A good way to make the request of a previous employer is a personal letter along the lines of the following:

John Doe, 100 E. Second St., Philadelphia, has applied to us for employment and refers to your company for his employment record as a machinist under Mr. Black, at \$42 per week, from January, 1921, to December, 1923, when he resigned for another position.

We shall appreciate and treat this information confidentially.

Such a request not only states clearly and briefly just what is wanted but also facilitates answering. It identifies the applicant; it states the essential points of the employment record as claimed by the applicant which can be readily verified and supplemented with a rating on workmanship, conduct and attendance. The data requested are sufficient to serve the inquirer's purpose. The option is offered of replying by memorandum on the letterhead or by

letter; it can readily be expanded to fit any unusual case or circumstance that may develop in any particular problem of selection.

There is no question but that the personal letter encourages more personal attention and care on the part of the informant than a printed form. It costs little, if any, more than a form and the increase is justified by the results in obtaining better information. Experience has demonstrated that there is a vast difference in the quality of replies between the questionnaire and the personal letter, favoring the latter.

In requesting personal references, a personal letter like the following can be readily expanded to cover special cases:

Mary E. Jones, 2310 N. 21st Street, Philadelphia, has applied to us for employment and refers to you regarding her character.

We shall appreciate your confidential opinion.

There are several grades of personal references with respect to their value in determining qualification for employment. There is the person whose name is furnished upon request by the applicant; it is often one who has no business or social standing and frequently only has a meager acquaintance with the applicant, so that such a source produces information of little value. Simply a name without any identity is valueless as a personal reference. The worth of anyone's opinion regarding an applicant's character and integrity after all depends upon his own character and integrity. Each person's rating is a relative matter, it depends upon the standard which he has in his own mind; so that after a rating is secured the problem remains of rating the person who gave the rating.

An applicant may be asked to give the name of a professional man such as a physician or lawyer, and even better a clergyman, or a man with whom he is personally acquainted who holds a position of responsibility in some reputable business, social, or political organization. Such persons, as a rule, have some sense of responsibility and are governed by a code of ethics which influences them not to give false endorsements or "glad hand" recommendations which would jeopardize their own standing.

Two Main Elements of a Reference. The two main elements of a reference are workmanship and character. Before proceeding with the reference checkings, it should be determined which of these should have the most weight.

For instance, in employing a field manager, whose work is to be mainly with schools, parents and children, *character* is the all important factor; previous business experience in workmanship is secondary. So the investigation is focused on character and this is given major consideration in the final decision. The net of this point is to decide what is the salient factor in the past record, then focus on it, not just to investigate aimlessly.

In attempting to evaluate a reference the source is important. An employment reference that confirms the period of employment and gives a satisfactory rating on workmanship and character from a concern that has a reputation for requiring high standards of workmanship and character should exert a deciding influence in the applicant's favor; likewise with a personal reference

that gives a clean bill of health on character and integrity from a person of some standing in the business world, such as a reputable banker.

As to the value of references, one thing alone has proven worth while in checking up previous employment records and that is: Misrepresentation is often disclosed, thus giving a lead to a weakness of character that would otherwise slip by.

When there is an apparent inconsistency between the claimed period of employment and the reference record the condition must be weighed on its merits, keeping in mind that common labor, and to some extent skilled labor, has a hazy recollection of time, dates and names. It does not reflect necessarily if there is an error made.

How much information should the inquirer expect, and how much should the employer answering feel obliged to give? A simple statement of the employment record is sufficient and, except in the case of high grade executives or salesmen, or in unusual cases where there is extraordinary responsibility involved, that is all that should be expected as a background to assist in judging the applicant's qualifications. The term employment record includes:

Period of service.

Occupation.

Wage.

Reason for leaving.

Rating on workmanship, attendance, and such personal qualifications as compatibility, loyalty, responsiveness to discipline and training.

After all, each employer must do his own judging of applicants and should not expect a former employer to do it for him. Simply because a man exhibits certain qualities and certain shortcomings in one organization is no indication that he will do likewise in another organization of different environment. Furthermore, just because a man does not work out satisfactorily does not mean that the good references which were obtained on him were off color.

Some employers, apparently, do not care to impart information about wage rates. If an employer holds back information about wage rates in answering a reference request, he is taking the best course to encourage false representation of wages by applicants. In other words, it is to the mutual interest of all employers to encourage a free exchange of information on wage rates.

When an employer receives a reference request from an inquirer with whom he is acquainted, when he knows that the information will be treated confidentially and how it is going to be interpreted and used, it is one thing; but if he has no idea as to how much or what kind of influence the information will have on the inquirer's final judgment, it is another. In the first instance, he can feel more free to go a little more into detail, perhaps to the extent of commenting on undesirable qualifications especially when he knows that the inquirer is broadminded enough to give the information the proper weight.

When an employer receives a request for a reference on an ex-employee he is immediately confronted with a twofold obligation; first, to his former

employee, to do all that circumstances justify to assist him in getting employment or such privilege as he is seeking, provided that it will be advantageous to him—it would hardly be a benefit to assist him into a position which he could not possibly fill. Second, as employer to employer, he will readily practice the golden rule if he will just reverse conditions and place himself in the inquirer's position.

Reference information should not be used as a "black list" by combinations of employers or otherwise which would work against the inalienable right of a man to the opportunity to earn a living. It is not uncommon to hear it said that such-and-such an employer will "blackball" a man if he leaves.

Unfavorable Data. When an unfavorable bit of information is secured the matter is not simply dropped and the applicant disqualified. Every effort is then extended to help the applicant clear up the matter. A man claimed five years' employment with a local reputable concern but their reference refuted his claim. The man was again interviewed and persisted in his claims and offered to call personally on his foreman and get a statement bearing out his claimed employment. He got the statement and it developed that a clerical error was responsible for the unfavorable reference. Frequently it is impossible to get any check-up on previous employers, especially in cases of casual employment. Then one must depend more on the character references and often supplement these with a personal investigation.

An ex-employee will sometimes ask a former employer if he has been referred to and what kind of a reference has been given when he has failed to land a particular job, and he may harbor a feeling that his former employer prevented him from getting it by giving a poor reference. In such cases it is helpful to have a copy of the reference which has been given to show to the ex-employee. There is no better way than this to clear up his reservations and maintain good will.

This brings up the importance of employers who ask for references keeping the information absolutely confidential. Many have had experiences where confidence was violated and the employer who so errs rarely gets the same brand of frank answers in the future.

Requests about Active Employees. Frequently an employer receives a reference request about one of his active employees. This is, unfortunately, embarrassing to both employer and employee. The employer forms the impression that the employee is dissatisfied and looking for a change, and the man's standing is weakened. The inquirer, as a rule, has no intention of jeopardizing the employee's relations with his employer and has made the request innocently thinking that the employee had left.

Some employers attempt to answer these requests in such a way as to prevent the inquiring employer from employing the subject, considering such a request as evidence that the inquirer is "stealing" his help. It would seem the mere fact that the employer is requesting a reference is, of itself, evidence to the contrary. Obviously if the motive were help stealing no such request would be made, as it would disclose the move. So when such a request is received, it should be answered by courteously informing the inquirer that so-and-so is still employed, is rendering satisfactory services, and is, apparently, satisfied.

Another way of looking at such requests is that they are valuable information; they indicate weak spots in the organization. If an employee is job hunting—and reference requests are undoubtedly evidence of it—he is due to cause turnover sooner or later, and the quicker this is found out the better for all concerned.

In merchandising it has long since proved poor selling to knock your competitor, and this policy applies to competition for labor. The employer is broadminded indeed who can, when one of his employees has an offer of a better job, part company saying, "We are sorry we can't offer you an equal one; good luck; if it does not work out, call and see us."

When a person is being interviewed for future prospects rather than an existing opening, the employer should be careful to ascertain whether everything is clear to look up references, before proceeding to the embarrassment of the applicant. Some applicants rightly object to any check-up prior to consideration for a definite opening.

References over the Telephone. Many concerns request references over the telephone. While this practice, no doubt, serves to expedite proceedings, there are several drawbacks. There is no assurance as to the identity of the inquirer, and while there could hardly be any objections to giving out the record of an ex-employee who was entirely satisfactory, there is a decided objection to giving out a bad record unless the identity of the inquirer is definitely established. When a telephone inquiry is received, if the inquirer cannot be identified and if the record of the employee is not thoroughly satisfactory, a good method of handling the case is to invite the inquirer to put his request in writing. There may be cases where an employer has information on an ex-employee which is of such nature that he would not care to put it in writing but would willingly pass it on by word of mouth if he were sure of the identity of the person with whom he was talking. Another objection to telephone requests is that unless the inquirer confirms his inquiry in writing, the person to whom the inquiry is directed has no record of the proceedings. In all cases the request should be confirmed by the inquirer, so that both parties may have a record of the transaction.

The Personal Visit. If a reference is particularly important, as with positions of unusual responsibility, and if the distance is not prohibitive, the most effective method is the personal visit. Employers who are reserved in their answers to written reference requests will be more inclined to "loosen up" when the information is sought through an interview, especially when the person who is calling is able to command confidence. Some employers make it a custom in seeking references of local employers to send a messenger with a form request. This accomplishes nothing except speeding up in comparison to mailing.

Letters of Reference. Many concerns give employees, when leaving, a letter of reference addressed "to whom it may concern." It is better when an employee leaves to advise him that one stands ready to write a letter to whomsoever may inquire, or to give him if he wishes, a simple written statement of his employment record, a pure reference without any recommendation. The first method seems preferable, because it saves the employer embarrassment with a poor record and he has more leeway to comment on the person in question if he so desires.

Use of Investigating Agency. An employee's record can be checked up through an investigating agency. A good agency can make an investigation bearing on standing in the community by calling on and interviewing acquaintances and stores in the neighborhood where the subject lives that will prove worth while information. But such an agency cannot obtain information from previous employers nearly so well as the employer can himself. Some employees will resent—not without reason—having an investigation made through some secret agency, but will hold no brief against an open follow-up by a prospective employer.

Requests for Credit Recommendations. Many merchandisers who extend credit and time payment privileges are in a habit of requesting credit recommendations on employees and ex-employees. With the recent growth of this type of merchandising these requests are on the constant increase in number. They are rather difficult for the average employer to handle. As a general rule, he is not qualified to judge whether his employee is or is not a good credit risk, as he is practically limited in his knowledge to the record of employment, which should be ample information for the credit investigator to expect from such a source.

Employees' Addresses. Most employers obtain their employees' addresses by requesting them on the application at the time of employment, frequently agreeing to treat the information confidentially. In such cases the course in answering requests for addresses is perfectly clear. But if this has not been so agreed, the best practice would seem to be: Before answering the request, consult with the employee to see whether he sanctions giving out his address, as it is obvious from the various purposes mentioned above that the information may fall into someone's hands to the employee's inconvenience or embarrassment. Some concerns avoid difficulties by answering address requests with this statement: "Employees furnish us their addresses and similar personal data with the understanding that we will treat them confidentially; therefore, we regret that we cannot comply with your request."

Legal Responsibility. It might be well to consider briefly the legal responsibility in connection with giving out information regarding an employee or ex-employee, and it would be advisable for each employer to seek legal advice so that his practice will not lead him into legal difficulties. It is hardly possible in a general way to cover this as the matter depends upon varying state laws.

This is how one legal mind views the matter:

Truth of the statements made is always an absolute defense to an action for libel. Further, even if the information furnished be untrue, the occasion may be privileged, which will likewise constitute a defense. When one is called upon to supply data in regard to a person who has formerly been in his employ and is about to be engaged by another employer who has requested the information, this constitutes a privileged occasion.

The foregoing is an accurate account of the theory of the matter. As a practical proposition, however, it must be remembered that the jury is the final arbiter of all facts and, therefore, one always runs the risk of failing to establish to the jury's satisfaction a defense of truth or privilege, no matter how plain the same may be. For this reason it is safe policy to require, as a condition precedent to furnishing any information, a release from the

employee in a form similar to the following, which effectually protects the person or corporation from all liability in the matter:

I request that you furnish to..... a full

Name and title	Address
----------------	---------

transcript of my record as an employee; hereby agreeing that same is furnished at my request and for my benefit, and expressly covenanting that nothing contained in said record (if anything) derogatory to my character or service, nor the furnishing of the transcript of the record, shall be in anywise excepted to or complained of by me, and that the said Company shall be in nowise answerable or liable to me on account of anything therein contained.

Another legal viewpoint is that the release is entirely unnecessary because an employee gives permission by implication through the very act of referring to a party voluntarily upon his application. It is sufficient defense against libel to prove that the information was given upon such a request and without malicious intent; the real danger is volunteering the information with malicious intent.

PLACING AND INTRODUCING EMPLOYEES

BY EARL B. MORGAN, *Consulting Engineer*

A great deal depends upon the manner and spirit underlying the way the introduction of the new employee is handled. It is hard to overcome bad first impressions even though subsequent developments show them to be unfounded. It costs little or nothing to put this principle into practice and it bears beneficial results. With a new employee, careful attention is required over the probationary period. This point becomes obvious when you refer to the turnover records of the average organization which generally illustrate the fact that the greatest turnover occurs during the first three months of the worker's service. Some concerns seem to think this principle of courteous and considerate treatment is applicable only to the higher grade help but experience has shown that the lowest grade help is just as susceptible to its influence.

Instruction. After the selection has been made the first thing in order is to see that the new employee is thoroughly instructed as to when and where to report for work. This, perhaps, can be best handled by the interviewer who selected the employee. If the manager (or foreman, that is to be in direct charge) has already covered his instruction during his interview with the employee, then what the interviewer does along these lines will serve to emphasize the facts and make sure there are no misunderstandings. It must be remembered that instructions to the new employee cannot be made too plain because the strange environment, meeting so many new people, and the process of employing itself, all tend to set the stage for misunderstandings which cause many to fail to report on schedule.

Particular care should be exercised to be sure that the newly selected employee understands clearly the terms under which he is to be employed.

These matters, of course, have been previously defined during the process of selection, that is, during the interview. But the average employee, when seeking a job, is a little nervous and this seems to make it very easy for him to get a mistaken idea about the terms of employment, and experience has demonstrated that later on no amount of explanation or proof by written record will satisfactorily convince the employee that he is being fairly treated; so there should be, at this time, a final confirmation, preferably by the interviewer who selected the employee, of the amount of wage for both regular time and overtime, also the hours.

A good method of insuring a clear understanding of the terms of employment is to have the employee sign a written statement of them which can be conveniently kept on the application or personnel record card.

During the process of selection it is, of course, important to explain the opportunities for salary increases and promotions but it is well during the instruction step of the placement process to take particular care that this is reviewed, because misunderstandings often occur which lead the applicant to think that these statements are promises. Whenever a definite promise is made, it should be written immediately on the employee's record and noted on a "tickler" so that it will not be overlooked when the date due comes around. To fall down on such a promise may seem like a very insignificant thing but it will quickly destroy the employee's confidence in the employer.

Information about the Company. The next step in instructing the employee is to inform him about the company, its business, its scheme of organization, its policies, its rules and regulations. In short, the new employee should be told what will be expected of him and in turn what he may expect of the company. There are two ways of accomplishing this—either by the oral method or by giving the employee a printed pamphlet or booklet. It is rather difficult in large concerns to take the time of both the interviewer and the employee to explain the many features that necessarily should be covered and the printed pamphlet or booklet is perhaps the best medium. If this information is distributed in printed form, it should be written in brief, clear and concise language. Printed forms can be made up in attractive pamphlets, such as a memorandum book, and illustrations are helpful. It must be kept in mind that the new employee is more or less nervous and in a confused state of mind due to the new surroundings and all that he is told during the first few hours of his employment usually produces rather hazy results, so at least for those who can read the printed pamphlet, that form seems to be the safest and most practicable method for large concerns.

Modern employment office practice dictates the necessity of keeping complete and correct personnel records for each employee. All information necessary for this purpose in the case of the new employee should be obtained in correct form at this time. Errors in spelling the name, incorrect address, and errors and omissions in the personal data can be corrected if these items are checked up before proceeding further. If a photograph is included in the record, or used as a method of identification, it should be taken at this time. A practice that seems to have merit is this: After a new employee is placed, mail to his home with a personal letter of welcome a copy of the firm's employees' magazine or paper.

Introduction. Up to this point everything should have been cleared up so far as possible so that when the new employee reports for actual work, there will be no interruptions necessary to take care of matters of detail.

If during the process of selection the new employee has been introduced to and interviewed by the manager, it will not be necessary for him to be personally introduced when he reports for work. If, however, the process of selection does not offer this opportunity, then there must be some method of introducing the employee to the manager when he actually reports. Any of the following methods are good and the one to be used simply depends upon the prevailing conditions: The interviewer personally conducts the new employee to the department; the new employee is sent by messenger who personally introduces him; the new employee is sent by messenger with a card of introduction; or the manager goes to the employment office to meet the new employee.

At this time the new employee should be shown by someone, preferably by the manager or at least one of his immediate assistants, all facilities for the personal comfort of the employee such as the lunch room, rest room, library, locker rooms, toilets, washrooms, drinking fountains, exits, fire escapes, and the method of keeping the record of attendance—time clock, and similar matters.

When the new employee actually reports in his department to go to work, he should receive immediate attention from the manager, the instructor, or whoever is to take care of him and not be compelled to wait as this often leaves the employee with a bad impression, makes him feel that no interest is being taken in him and tends to discourage him.

Some concerns have adopted the practice of taking the new employee on a trip through the plant during the first few days of employment, others have the plan of giving group talks to new employees on company policies. Both plans probably have their merits in certain situations, but before deciding upon such a plan it should be remembered that the new employee is generally confused when he starts to work and trips through the plant and talks are liable to add to his confusion rather than assist him. These plans are more or less expensive, involving a great deal of time and money, and it is questionable whether they pay their way. In general, the more quickly an employee is settled in his job, the more quickly he can gain self-confidence and get over that "first day at school" feeling; then perhaps after he is settled, a trip through the plant would be more beneficial.

Reception Committee. The idea of having a reception committee to get the new employee started on the right track seems to be used to some degree of success in various organizations. This plan is generally worked out by having a representative in each department to act as "sponsor" for the new employee during the first few days—introducing him to the fellow workers and the environment. This plan undoubtedly has some advantages, but like all other personnel practices, it should be weighed as to its fitness under the given conditions before it is adopted. There is some danger that certain types of employees would feel an undue paternal influence if someone was detailed "to be a big brother" to them. Then there is this to consider, should it not be the manager's or foreman's job, and does he not owe the employee

this much interest and attention? And by giving it, would he not cement relations right at the start?

Where a large number of girls are employed, it is quite necessary to have some person, particularly if there is a male supervisor, to whom the girls can go with certain problems which they would not be free to discuss with a male manager. This situation is often met by having a woman in charge of a so-called service division who is ready to help girls in such situations.

Follow-up. In order to round out a well planned and well executed program of selection and placement it is essential to check up on the success of the selection as soon as the employee has had an opportunity to demonstrate whether he has the necessary qualifications to fit the requirements. The period of service necessary to demonstrate fitness varies for different positions but in most cases one month at the most should furnish sufficient time. However, the check-up should be made as soon as possible so as not to allow an employee with inadequate qualifications to linger on the job longer than is necessary. A poor selection only ceases to be a liability when replaced by one who is qualified.

There are several ways of going about this matter of follow-up of new employees:

1. The interviewer personally investigates and interviews the new employee on the job. He is thus afforded an opportunity through personal contact with the interviewer who selected him, to tell about any unsatisfactory conditions which may have developed, and also that the new employee is impressed with the fact that the interviewer has a personal interest in him.

2. The new employee is asked to call at the employment office for interview.

3. The interviewer discusses the progress of the new employee with the foreman only, because it is felt that the interviewer may otherwise be considered by the foreman as meddling with the foreman's authority and weakening it, and furthermore, that the interviewer will become involved in trivial grievances of the employee that would otherwise never come up.

As to there being a chance of creating a feeling in the foreman's mind that there is someone attempting to come between him and his men, this may seem a rather trivial matter but the employee frequently thinks that the employment interviewer is the person to whom he must turn rather than his own foreman after an investigation by the interviewer. Of course, the new employee should be assured that the interviewer will be glad to see him at any time in the future if he wants advice or assistance, but in handling such cases the interviewer should be very careful that the foreman is fully advised of what is going on.

4. Some advocate that the interviewer follow up the new employee's progress with both the new employee and the employee's foreman or manager in order to get both viewpoints. The advocates of this plan claim that both sides of the case are necessary in order to thoroughly size up the situation.

Whether or not the new employee is to be approached in the follow-up investigation, there seems to be no argument against the statement that the foreman, or manager, should be. If, for no other reason, it makes him appreciate that the interviewer is trying to cooperate with him in obtaining the best possible personnel and tends to bring them both closer together.

5. The interviewer does not make a personal investigation by interviewing either the foreman or the employee but relies upon a written report or rating from the foreman. This method is felt to be rather "cold" and devoid

of any stage setting or environment of the job, and does not afford personal contact. The interviewer's job information is strengthened if he goes right out on the ground and sizes up the situation himself. If he does this, then any written report which is submitted would seem to be strengthened.

One point is often overlooked by those who have perhaps become over-enthusiastic about system, in particular a few writers who advocate employment plans and policies which are nice in theory—and that is the matter popularly known as “red tape.” There are some employment offices particularly in large concerns where a new employee has to go through such an extensive system that he becomes bewildered and annoyed to the extent that either he loses his respect for the firm or gives up completely in disgust.

As to whether any system leaves an undesirable psychological effect upon the new employee depends in a large measure on the spirit in which it is administered. Any system coldly handled will fail; whereas a system which perhaps may be a trifle complex can be used without creating resentment by humanizing it.

LABOR TURNOVER

BY LLOYD R. MILLER, *Policyholders Service Bureau, Metropolitan Life Insurance Company*

Is Labor Turnover a Problem? The condition involved in the hiring, loss, and replacement of a company's working force is known as labor turnover. This condition usually means waste, because money and time are required to hire and train new employees. Experience proves that a part of turnover is preventable, and that some types are more costly than others. The first questions to be considered by any one charged with the responsibility for turnover are:

1. Is the turnover normal or abnormal in amount?
2. What is a conservative estimate of its cost?
3. Are the extent and cost of turnover sufficiently excessive to warrant further attention?

How Large Is Turnover? There are many formulae for computing turnover and much controversy still exists as to which is most suitable. At this point, however, a simple measure of one aspect of turnover is usually satisfactory, for example, the total separation rate, or $\frac{S}{P} 100$. Here, S is the total number of separations during a given period and P is the average number of persons on the pay roll. With this formula, a series of monthly total separation rates can be obtained for a period such as the past year.

Is Turnover Abnormal? The next step is to compare this series with a norm or standard to determine whether it is low, high, or average. In the case of the factory industries, standards are provided by the U. S. Bureau of Labor Statistics in the form of indexes of labor turnover.¹ The bureau also

¹ This project was undertaken and for some time continued by the Metropolitan Life Insurance Company, which transferred it to the Bureau in July, 1929..

compiles similar indexes for certain industries. Whenever suitable standards are not available, the best plan is to secure the experience of several comparable companies.

How Much Does Turnover Cost? Lastly, a rough estimate of the cost of turnover is advisable. This will take into account such items as: employment office expense incident to hiring and placing, training expense up to the time when an employee can learn his new job, and losses due to spoilage and to increased wear and tear on machines and equipment. It is usually a good idea to make separate estimates for skilled, semiskilled, and unskilled jobs, and to note to what extent each type of job contributes to the total number of separations. With this information at hand, conservative, minimum cost estimates are possible and intelligent decision can be made as to the amount of attention turnover requires.

What Causes Turnover? Assuming the preliminary analysis indicates that turnover is a problem of some importance, a consideration of causes is in order. Employees are first hired; some of them stay with the company, others quit, are discharged, or laid off because of lack of work; then replacements are made by further hiring. These phenomena can be measured by hiring or accession rates, stability rates, quit rates, discharge rates, lay-off rates, and replacement rates. Each of these rates measures only one phase of the condition known as turnover. Consequently, in this discussion, the term turnover refers to a condition rather than to any single measure of that condition.

In so far as separations occur on the initiative of individual employees, the causes are as complex as the motives which stimulate human action. Economic, health, family, and personal considerations—all have a part in determining the final action of an individual. Separations due to managerial initiative are usually traceable to economic conditions, managerial policies, and the quality of supervision.

Consequently, while it is impossible in most cases of separation to single out a specific cause, yet it is possible by an analysis of several hundred separations to learn many of the outstanding reasons which together have brought about the general condition known as turnover. With this knowledge at hand, constructive measures can be taken.

The Exit Interview. Fundamental to the keeping of reliable records of labor turnover and analyzing its causes is a procedure for interviewing employees immediately prior to their leaving the company. The type of organization will determine who conducts these interviews. It is important, however, to have a person who commands respect and confidence, and who is tactful, just, understanding, and a good listener. It is also helpful to have privacy and quiet.

Those who interview employees have a threefold function:

1. To learn all pertinent facts about each employee and his reasons for seeking employment elsewhere.
2. To give information, whenever advisable, regarding opportunities in the company and how the employee may best take advantage of them.
3. To serve the employee, taking into consideration his own best interests and the interests of the company, and consequently, creating goodwill toward the company.

1112 HANDBOOK OF BUSINESS ADMINISTRATION

It is usually advisable for an interviewer to prepare himself with sufficient information to enable him to discuss intelligently whatever problems arise. The following outline will indicate useful data, most of which can readily be obtained:

- A. The individual and his personal problems.
 - 1. Age.
 - 2. Nationality.
 - 3. Sex.
 - 4. Education.
 - 5. Marital status.
 - 6. Number of children.
 - 7. Other dependents.
 - 8. Other members of the family employed in this company.
 - 9. Length of time in the community.
 - 10. Home owner or tenant.
 - 11. Other sources of income.
 - 12. Previous experience.
 - a. Jobs held and length of time at each.
 - b. Reasons for change.
 - c. Have changes meant advancement?
 - 13. Physical condition.
- B. Previous record with the company.
 - 1. Department.
 - 2. Job.
 - 3. Rate of pay.
 - 4. Hours.
 - 5. Length of service.
 - 6. Special training in the company.
 - 7. Transfers.
 - 8. Increases in wages.
 - 9. Bonus record, if any.
 - 10. Attendance.
 - 11. Ratings.
- C. The present problem.
 - 1. Reason for leaving reported by immediate superior or department head.
 - 2. Would department head recommend reemployment? Why?
 - 3. Other comments by department head.

While no hard and fast procedure can be suggested, it is, of course, the first duty of the interviewer to try to understand *why* the employee is leaving. The reason first given is not the true one in many cases, and the truth can only be learned by obtaining all the available information about the employee, his job, his relationships with others, and then trying to put one's self in his place. The interviewer must use his judgment in determining what facts will be useful. The following outline may suggest some of the supplementary information which may be obtained during the course of the interview:

- A. What is the employee going to do after he leaves?
 - 1. Has he secured another job?
 - a. If so, what is the name of his new employer and address? What is the new job, the pay, the hours, the future?

- b. If not, has he considered the possible difficulty of locating a job and the result of unemployment while doing so both upon himself and his family?
- B. What is the employee's attitude toward this company?
 - 1. Would he advise any one else to work here? Why?
 - 2. What future does he think there would be?
 - 3. Would he ever want to work here again himself? If so, in his old department?
 - 4. Has the employee any suggestions for improving working conditions, inequalities in rates and methods of pay, supervision, training, etc.?
- C. Would the employee like our help in securing a job somewhere else?

One problem is to get in touch with an employee immediately at the time of leaving. The accepted practice is to require a *clearance form* originated by a department head or foreman and signed by the employment department before the final payment of salary or wages is made.

Analyzing the Causes of Turnover. The findings which result from exit interviews may be analyzed in many different ways. A satisfactory method used by many companies is to post the information regarding each separation under the proper classifications on a form such as is shown in Fig. 1. An analysis of separations by months and by departments is helpful, and the questions shown at the foot of each column usually suggest further subjects for investigation.

A few hints on keeping this record and analyzing it follow:

- 1. Be sure that every employee is interviewed before leaving. Require an O.K. from the interviewer before final pay-off.
- 2. Check up doubtful cases to see if the reason given by the employee and his immediate superior tally. If not, further information and the exercise of good judgment will be necessary.
- 3. There may be several reasons for leaving. Check the one you think most important and note further details, if necessary, to help you recall the case.
- 4. It is most important to decide whether an employee is discharged, laid off, or quits voluntarily.
- 5. Do not confuse discharges for incompetency with those made for disciplinary reasons. The former implies improper selection or placement; the latter may indicate faults in the supervisory force as well as in the employee.
- 6. Do not conclude that the reason "leaving for a better job" always means competition in the labor market. Some employees are inclined to give this reason to conceal the real one. Find out, if possible, just what the better job is and how it is better.
- 7. Consider each exit from the company in the light of previous experience as shown by the analyzed record to date and take any necessary action at once.

Economic Causes. Economic conditions have a much more important bearing on labor turnover than is frequently realized. The ebb and flow of general industrial conditions bring about alternate increases and decreases in orders for manufactured goods. These cannot be produced without raising the accession rate, and consequently the volume of employment, the lay-off

rate meanwhile declining. But as the volume of employment increases, the surplus available for hiring dwindles and the labor market becomes a "sellers' market." Almost any one except the unemployable can find some sort of job, and the man who already holds a job can find around the corner plenty of others offering to him real or imaginary advantages. Hence, arises a rapid and violent increase in the quit rate in a period of rising rates of production. Intimately associated with this is the fact that heavy accessions naturally load the force with short service employees, among whom the quit rate is well known to be higher than among employees of longer standing. In contrast, when prosperity gives way to crisis, liquidation, and major or minor depression, lay-off rates rise. Accessions and the volume of employment diminish. Quit rates almost at once decline, partly because the bottom drops out of the competition for labor and partly because the laying-off process has removed a larger proportion of short service than longer service employees with their better "persistency."

Through the use of various indexes¹ constructed by the United States Bureau of Labor Statistics, it is possible to form a more intelligent opinion as to the effect of economic conditions on the labor market and hence on an individual company's turnover experience. Sometimes, it is possible to make comparisons with the experience of separate industries and localities. The United States Bureau of Labor Statistics now constructs turnover indexes for the following industries: automobiles, boots and shoes, cotton manufacturing, foundry and machine shops, furniture, iron and steel, saw-mills, and slaughtering and meat packing. Through cooperation with state and local agencies, statistics are also available for factory industries in a number of states and cities individually.

Internal Causes. Changes in managerial, sales, production, financial, and industrial relations policies and practice all may have their influence on labor turnover. Yet, the significance of such changes frequently is not realized. As an aid in interpreting the course of each turnover variable, it has been found useful to keep a monthly record of major changes which occur. The following list may be helpful in keeping such a record.

Major Changes in Company Policy or Practice

A. General and financial changes.

1. In organization functions and executive personnel.
2. In affiliations (including mergers, subsidiaries, etc.).
3. In product.
4. In plant, buildings, and equipment.
5. In budgeting.
6. In executive decisions based on prospects of business.
7. Unusual events (such as fire, flood, epidemic).

¹ For method of constructing indexes, see William A. Berridge, "Measuring Labor Turnover," *Personnel Journal*, October, 1929.

For change in method, see *Monthly Labor Review*, U. S. Department of Labor, p. 134, March, 1931.

For standard procedure of reporting turnover, see *Monthly Labor Review*, U. S. Department of Labor, pp. 99-100; December, 1929; p. 91, January, 1930.

B. Marketing changes.

1. In sales promotion.
2. In personnel.
3. In distribution.
4. In price.

C. Production changes.

1. In process.
2. In machinery and equipment.
3. In scheduling and routing.
4. In departmental organization.
5. In supervisory personnel.
6. In purchasing.
7. Unusual events (as breakdowns, shortages of materials, etc.).

D. Industrial relations changes.

1. In wages and hours.
2. In employment practice (such as sources of labor, selection, transfer, promotion, discharge, lay-off, etc.).
3. In joint relations.
4. In health and safety.
5. In working conditions.
6. In training.
7. In economic security (such as group insurance, savings, stock ownership, profit-sharing, etc.).
8. In service activities (such as cafeteria, cooperative store, social and recreational activities).
9. In community conditions (housing, transportation, cost of living, etc.).

Reducing Labor Turnover. A minimum of labor turnover is normal and desirable in order to keep open avenues for promotion and to stimulate ambitions and new ideas. But instances of companies confronted with this problem are rare.

A sound procedure for labor turnover control, which in most cases means reduction, has the following essential steps:

1. *Get the facts* through observation, exit interviews, analysis of the causes of separation, and comparisons with available indexes.
2. *Interpret the facts correctly* through studies of the cost of turnover, records of internal changes, and discussions with supervisory officials.
3. *Create an active interest* on the part of the chief executive and see that his interest is known to every one in the organization.
4. *Provide a directing force.* The manager of the personnel department, if there is such an official, is usually the best person to provide direction.
5. *Maintain the active cooperation of executives and supervisory force* in solving the problems which are revealed.
6. *Take definite action.* Study and analysis alone will not reduce turnover.

In following such a program, there are three distinct types of responsibility from an organization standpoint: (A) those of the major executives, (B) those of the executive responsible for personnel, and (C) those of the supervisory force. Taken in order, they are:

A. Responsibilities of major executives.

1. See that labor policies are sound.
2. Stabilize employment by giving careful attention to stabilizing sales and production.

3. Hold the foremen accountable for departmental turnover records.
4. Impress upon the organization the importance of turnover as a cost item. Point out relationships between low turnover and good production whenever possible.
- B. Responsibilities of executive in charge of personnel.
 1. See that employees are selected and placed with the greatest care.
 2. Maintain close personal contact with supervisory force. This will help in taking care of future labor requirements, arranging for transfers, and reducing the number of lay-offs.
 3. Have a promotion policy.
- C. Responsibilities of supervisory force.
 1. Take a personal interest in employees. Demonstrate this interest by seeing that each person receives all the benefits to which he is entitled. Study men, their qualifications, and peculiarities to avoid misfits.
 2. Develop good workers. Be particular about training new employees and getting them started right. New employees are those most likely to become dissatisfied and leave. Train the older employees for better and more difficult jobs so that they can be advanced when conditions warrant.
 3. Provide good working conditions. A supervisor has considerable control over safety and sanitation in his department. See that the ventilation and lighting help to increase production and satisfaction with the job. Discourage cliques and promote a "friendly atmosphere." Call attention to conditions outside of departmental control.
 4. Give a square deal. Do not show favoritism.
 5. Let employees know what they must do to be in line for promotion.
 6. Review earnings of individual employees. If the basic rates need adjustment, report the matter. Piece workers sometimes have low earnings because of poor scheduling and routing of material or improper tool equipment.
 7. Adjust complaints and grievances. Clear up misunderstandings and false rumors. Many complaints can be handled without embarrassment to any one. Present management policies in an understandable way.
 8. Avoid unnecessary lay-offs. When lay-offs are necessary, notify the employment department sufficiently in advance to arrange for possible transfer.
 9. See that employees do not leave without your knowing why. Report your opinion on each case to the exit interviewer.
 10. Cooperate in improving conditions revealed by studies of the causes of leaving.
 11. Develop leadership. Employees respect and stay with a leader whom they feel is looking out for their legitimate interests.

PRINCIPLES INVOLVED IN THE PAYMENT OF DISMISSAL WAGES

By E. H. LITTLE, *Assistant Supervisor of Industrial Relations, United States Rubber Company*

Definition. A dismissal wage is a payment to an employee of salary or wages beyond the time that employment has been terminated by the employer. Such payment may be:

1. Full or part pay for a stipulated period of time.
2. Cash payment in a lump sum at time of dismissal.

Conditions under Which Dismissal Wages Are Paid. Dismissal wages are usually paid under definite conditions where a pension policy is already in effect. The payments are made to persons of long service who fail to meet pension qualifications. These conditions are:

1. *Consolidations or mergers*, resulting in the discontinuance of operations in a given locality.
2. *Changes in products*, resulting in the discontinuance of certain skilled jobs.
3. *Changes in processes*, where older employees cannot adapt themselves to the new methods.
4. *Physical or mental disability*, in cases where employees lack age or service qualifications for a disability pension.

Along with the adoption of the policy of paying dismissal wages, we usually find the company assuming the responsibility of trying to place employees who are being laid off. Local contacts are used to locate other industries which are adding to their forces and employees are directed accordingly.

Reasons for Paying Dismissal Wages. The reasons for paying dismissal wages can be classed under two heads, moral and economic.

Moral Responsibility. As hiring age limits have been more generally put into effect, the individual industry has recognized its responsibility for caring for the employees who have grown old in its service. Furthermore, when an employee, through no fault of his own, loses his job after long years of continuous employment, the period of adjustment is necessarily difficult. He does not know the art of job hunting, nor is he adaptable in acquiring the knowledge of a new industry and learning the work habits of a new job. The dismissal wage helps him to "carry on" through this adjustment period and permits him to exercise some selection in choosing his next job instead of being forced to accept the first thing that is offered.

The pension itself provides a second moral responsibility. For employees, it is a stabilizing factor. Better immediate opportunities without old age security may have been disregarded in the past. With the loss of this job goes that security at a time too late in life to build up service elsewhere.

Economic Reasons. When a dismissal wage is paid in the event of changed methods or changed products, we must consider what would be the effect of not paying it. Laying off a long-service man without any such payment would result in adverse reactions on the part of other employees. As a consequence, resistance to new products and new processes would be built up, which would add to the cost of their introduction. Retaining the man who cannot adapt himself to new conditions and who becomes a block in the way of progress is only another phase of inefficiency.

There is a second economic reason: Public opinion generally is ready to criticize the industry which does not care for its long-service people. Where public relations is a business asset, the dismissal wage is a factor in warding off the unfavorable reaction which would otherwise result from such lay-offs.

To Whom Dismissal Wages Are Paid. As previously stated, the dismissal wage has usually been adopted as an adjunct to a formal pension plan which provides for monthly payments based on earnings and length of service for the remainder of the employees' lives. The provisions of pension plans usually specify twenty to twenty-five years of continuous service and from fifty-five to seventy years of age. Such pension plans have tacitly granted a responsibility toward employees who were eligible both with regard to years of service and age. It is difficult to distinguish between them and the employee who lacks one of the two qualifications. Thus we see growing up a similar feeling of responsibility particularly for the employee of pension age, lacking service; and for the employee with ample years of service, but not of pension age. When, therefore, the conditions specified in a preceding paragraph arise, we find the more forward looking companies adopting a policy of making a termination payment to such employees.

As the pension plan takes into consideration both age and length of service, so we find the same factors figuring in dismissal wages. Some companies provide for dismissal wages after two years of service, but more frequently ten or fifteen years is the requisite. Almost universally we find some account taken of age. For those over a certain age, forty-five being the youngest noted, the service qualification is lowered or the unit of payment increased.

Factors in the employee's record other than age or length of service are not taken into consideration. The assumption has been general that if the industry has retained the employee for a sufficient number of years to make him eligible on the basis of service, the time is past for considering differences in workmanship or general value to the industry.

Lump Sum vs. Extended Payments. Both methods are used. From the point of view of the employer, the former is better since it terminates all relations with the employee at the time he leaves, and the large single payment makes a more favorable impression. On the other hand, it is true that many of the employees spend the large amount unwisely, being unaccustomed to having on hand at one time a sum of money of this size.

The Amount of the Dismissal Wage. The most common formula for figuring the dismissal wage is one week's pay for each year of service. There are companies which give half pay for as many months as the employee has years of service and others that pay an additional number of weeks pay for each year of service in excess of fifteen years to employees of advanced age. In some instances the formula varies definitely with regard to age, length of service, and reasons for termination. The most generous policies, as would be expected, are those applying to total permanent disabilities.

The week's pay is a definite figure in the case of a salaried employee. This, however, is not so with a wage earner. The practice has been to take average weekly earnings over a considerable period of time. The income tax card is useful for this purpose. If the average is for a whole year, weeks of absence, either due to sickness or lay-off, should be deducted. Where it is understood that the payment is on the basis of a week's pay, it is important that the figure used, to be multiplied by the years of service, looks like a week's pay to the employee.

Continuous Service. In almost every instance the payment of a pension or a dismissal wage is based on years of continuous service. This means that records of service must be accurately kept and consistently interpreted. The latter is almost as important as the former. To insure this, a continuous service policy must be formulated. Such a policy should cover the following:

1. *Definition.* Listing of absences which do not constitute a break, such as, leaves of absence, sickness, injury, or temporary lay-off.

2. *Length of time service is protected* in case of the above absences (frequently one or two years).

3. *Deductions.* Limit of absence before deduction from length of service is made for the absence.

4. *Method of Handling Military Service.*

5. *Reinstatement.* Procedure for recording reinstatement of employee upon his return, when previous service has been protected.

Service Records. Records of age and service are very important in the administration of insurance, pension, and dismissal wage policies. One of the principal functions of such policies is the good will engendered. This may be almost wholly destroyed by inaccuracies in records which materialize at the time that the policy affects the individual employee. It is considered good practice to maintain individual service records, which the employees sign at stated intervals, and to keep these service records in a fireproof vault.

Benefits Derived from the Payment of Dismissal Wages. These can be enumerated under three heads.

The Company. Favorable reactions from all employees, as well as from direct beneficiaries, frequently resulting in more efficient operation, readier acceptance of changes, improved quality of product, and avoidance of waste. Favorable reactions on the part of the local community, resulting in better public relations and an appeal to higher types of labor.

The Individual Receiving the Wage. Economic ability to tide over an adjustment period, which is almost as important from a psychological as from an economic point of view.

The Local Community. Projection of the buying power of the persons receiving the wage over a longer period. In some instances, this may avoid a drain on relief agencies. The favorable community reaction results in a direct return to the company of greater cooperation in placing all employees who are being laid off, and to the whole community in a quicker absorption of the unemployed.

SELECTING AND PLACING COLLEGE GRADUATES IN BUSINESS

BY JOHN MILLS, *Director of Publications, formerly Personnel Director, Bell Telephone Laboratories, Inc.*

Why do we want to employ college graduates? Is it because of certain technical ability, whether in lines of economics, accounting, writing, science or engineering, which he has acquired from his college courses and of which

we may make, in our business, immediate use? There may be differences in the reply to this question, but for myself the reply is "no." The college should not be a trade school for industry, and all attempts to make it such by the inclusion of courses of specific industrial applicability are likely to destroy its value in our social and economic life. Are we, on the other hand, in the employment market for college men because everybody else is and we assume we are all on the right track? There is an element of this, and there is a danger of neglecting to develop, by educational opportunities within industry, the man of equal native ability who cannot attend college.

Are we interested in college men because of a greater adaptability and ease of training for many of the routine and repetitive tasks of our business and industrial world? Of such a demand in the past there has undoubtedly been too much. It usually reflects the absence of adequate training facilities for less immediately acceptable employees. It is possible that supervisors or intermediate executives may at times demand for certain of the tasks of their departments more highly trained men than they really require because they are either impatient of incompletely trained assistants, or incompetent of giving through their executive supervision the further training which is necessary. Let us put this question in another way. Are we interested in the college man because we haven't in our own ranks at any time a sufficient number of men capable of advancement, or because we haven't the time to select and train those we believe are equal in ability to the average college man we hire?

After we have answered these questions we shall probably agree that we turn to the colleges in the hopes of obtaining men of good mental ability and personality, who have acquired habits of thought and study which will enable them to see broadly the business and technical problems of the future, to analyze the factors involved, to arrive objectively and without prejudice at solutions, and through personality and executive ability to give those solutions weight and effectiveness.

I believe in this case in writing specifications for the man and not specifications for the job. For the more routine, repetitive, and standardized tasks of industry, job specifications may be written, but when it comes to employing in the hope of obtaining the future creative genius or far-seeing executive, we must work to man specifications.

Specifications for the Employment of College Men. The first is that of "intellectual curiosity." Under this term we include not the casual and idle curiosity of the feeble and twittering mind but rather that sort of curiosity which leads to a continued and orderly effort to determine the why of the physical or social phenomena of the world about one.

The second requirement is the "ability to study." It is perhaps the one real aim in education; but the percentage of the population which has the ability to study is much less than the percentage of academic degrees or similar evidences of learning would appear to indicate. Learning looks to the past while study looks to the future. In the first meanings given by the familiar authority of Webster, "learning" is "gaining knowledge, understanding, or skill" while "studying" represents "applying the mind" and acquiring knowledge "by one's own efforts." It is this ability to apply one's

mind and acquire knowledge by one's own efforts which the college man that we want in industry must have acquired.

The third requirement is the "habit of study." Apparently this is a habit which takes time to acquire and the four years of a college course have frequently proved insufficient time.

The three remaining specifications have to do with the student's attitude and abilities in human relationships. The fourth requirement in our specifications is, therefore, the ability to learn from men. The fifth is the ability to cooperate with men; and the sixth the promise of ability to lead and influence men. These last three requirements in the specification are placed in this order, because the ability to learn from men is the most important, and, if inherent in an applicant for employment, must in time lead to an ability to cooperate with men and a basis of trust and confidence which will provide opportunities for leadership. These are the main specifications which business and technical industries should try to satisfy in hiring the product of our colleges.

Determining the Qualifications of an Applicant. Having established the specifications we must next set up a method for determining whether or not the applicant is sufficiently within the limits of the specification to warrant employment.

In the selection of a candidate for employment there are three questions to be answered: (1) Along what lines of endeavor lie his fundamental interests and urges? That is, what are his aptitudes? (2) Has he the mental foundation to produce in this line? And (3) has he the personality, character, and physical qualifications for such productive work?

In selecting men the interview method is best although it has its obvious limitations. In such interviews the greater part of the time and effort is expended in arriving at an answer to the first question and the answers of the remaining two questions are by-products, that is, judgments formed very largely during the answering of the first question. Of course, in the case of college graduates it is always possible to obtain reliable records as to their accomplishments during the past four years both in academic work and in campus activities. These supplement the interviewer's judgment in answering the second and third questions. A part of the interview is usually, however, spent in obtaining directly some indication as to the applicant's mental ability; and the method of so doing may well be described.

Importance of an Unhurried Interview. As far as possible the interview is unhurried and devoid of the brusqueness of an oral examination or inquisition. The outline of the applicant's college work and campus activities is usually at hand in the form of a filled-in employment application. The interview should be as far as possible an essentially social meeting of an older college graduate with a more recent graduate, in which the older man may make friendly inquiry as to the college experiences and interests of the more recent graduate.

The conversation proceeds more or less naturally, but guided by frequent questions of the interviewer. The naturalness is greater, of course, the greater the possible allowance of time. Time, too definitely limited in advance, tends to make the questions of the interviewer too consecutive and

continuous and even to sharpen them; all of which is unfortunate and detracts from the free association of ideas which is desired. At some point in the interview some subject, which has thus naturally come into the conversation, is taken up by the interviewer for a little more intensive discussion. It may arise from a mention of some professor whom both know, from the description of some course of study which the applicant has had, from some summer employment in which he was engaged, from the mention of a book or a theory with which some professor was concerned, or, if time is short, it may be somewhat artificially injected into the conversation by the interviewer.

The subject which is thus taken up for more intensive discussion should be one with the fundamentals of which the applicant is presumably familiar; and to assure this they may even be stated by the interviewer as his contribution to the conversation. This means also that the chosen subject must be entirely familiar to the interviewer. It should, however, pertain obviously to the past experiences of the applicant rather than to those of the interviewer. The mention of this subject gives rise on the part of the interviewer to a question which has presumably not been met before by the applicant, but the logical discussion of which should be within his possibilities. Preferably it should be a question which does not permit of a categorical answer but requires an analysis of the factors upon which a correct solution would depend. By the thought processes and methods and by the lucidity of expression and promptness of comprehension of the applicant, while discussing this question, the interviewer may arrive at his own judgment as to the applicant's ability to study things out.

In this connection it cannot be too strongly emphasized that the question must not call for information in its answer, must be in a line in which the applicant has already expressed an interest, must be sufficiently familiar to the interviewer so that he may guide the conversation by a sort of a Socratic method, and preferably should have arisen in a most natural and conversational manner. If the interviewer is himself properly informed on the factors involved in a consideration of his own question he should be able to add, conversationally, facts or points of view which will arouse and test the curiosity of the applicant.

This method has been applied by a number of very successful executives. When properly handled it cannot be beaten by a prearranged set of answers, nor by an assumed attitude on the part of the applicant. There is no preparation which can be crammed to meet it. On the other hand, it cannot be reduced to a formula to be applied by an inexperienced employment clerk. The men from whose interview of myself I picked up the idea of this method were in widely different lines of work, one a college president and the other an executive in a large engineering industry; but both were broadly cultured and widely read. In order to practice the method to best advantage with arts college graduates it is usually essential that the interviewer should have a good background in science, economics, and psychology, with some interests in history or literature. For graduates of engineering schools, the sciences of physics and chemistry, with some knowledge of mechanical, electrical, and chemical engineering, form a satisfactory background.

This interview method which arrives by free association of ideas at something from which the interviewer can make a judgment is the method in which I, personally, have greatest faith for determining whether or not an applicant for employment has the intellectual curiosity, and the ability and habit of study, which are half of the six "man specifications." As was said before, it also affords opportunities for judging the last three of the specifications.

Determining the Aptitudes of an Applicant. We all know how applicants tend to have acquired certain individual prejudices as to types of work and express preferences which are misleading and usually inadequately representative of their own interests. In an attempt to avoid this state of affairs, and to get below the surface of these somewhat conventional preferences, I have for some time been using for technical school graduates a method which was described in the *Journal of Personnel Research* under the title "Engineering Aptitudes."

The method involves asking the applicant some four definite questions with, of course, such supplementary ones as the conversation may later require. These force him to express in abstract terms his more or less instinctive interests. In the paper previously mentioned these questions are phrased for technical school graduates whose training as you know is rather set and definite. I have not yet arrived at equally definitive questions for arts college graduates whose training varies widely. For arts college men it is necessary to vary and adapt the phraseology of each question to fit as nearly as possible the situation of each applicant. I shall, therefore, only outline the questions in abstract terms, without supplying definite phraseology and allow you to consult the original paper if you desire to judge the method from its technical school form.

Questions Which Indicate Aptitudes. The first question assumes that the applicant is looking for a job which will lead to a career, that is to the expression of his personality through some medium, just as an artist chooses a medium for his self-expression. For this let us assume four media, namely those of (1) ideas, (2) men, (3) things, and (4) economic symbols. The philosopher has his career almost entirely in the medium of ideas, a politician in that of men, a mechanic in the field of things, and a statistical economist in that of economic symbols. But there are combinations of these fields with primary and secondary interests; thus a good teacher is usually interested in ideas and men; a business promoter in men and economic symbols; a research scientist in ideas and things; and so on. It is illuminating to have each applicant write these four media in his order of relative interests. When that is done, and leaving out of account certain typical arrangements which are common to the engineering and scientifically minded, we usually find the salesman or business manager type expressing his preference in the order of men, economic symbols, things, and ideas. The type to be concerned with the management of technical processes expresses the interest as men, things, ideas, and economic symbols, or as things, men, ideas, and economic symbols, if he will take more interest in the equipment than in the human beings with the management of which he is concerned. The advertising man, personnel worker, and the like will be in favor of the order:

men, ideas, things, economic relations. And the expert on costs and accounting in the order: ideas, economic symbols, men, things. Several cross check questions which may be used to supplement this question may be easily devised. They serve also to lead to somewhat finer differentiations.

Another question asks as to the applicant's preference between technical responsibility and supervisory responsibility, assuring him that both types are equally rewarded, in salary and opportunity of promotion, for similar contributions to the welfare of the company. The men who put ideas high in their list will express an instinctive tendency toward technical responsibility and those who should not be placed in jobs calling for the development of technical judgment will choose supervisory responsibility. The expert buyer may well express a high interest in things and ideas, while the successful salesman is interested in men and economic symbols.

Cross-check questions can be formed and gradations recognized. Another question may be of interest: one which has to do with motive. We assume that as human beings we are driven to make such successes as we do by virtue of three motives, namely, an economic motive, which is the desire for more and more of the things of this world; a motive of ambition, which is interested primarily in acclaim and credit; and an instinct of workmanship, which is the play instinct grown up, a motive which finds its satisfaction in the activity itself, and at the time, rather than in results which follow. We may then ask what the applicant estimates are the relative proportions of these three urges in his own make-up. The management type runs high, apparently, in the motive of personal ambition, somewhat less in economic motive, and very little in the instinct of workmanship.

Labor Turnover in Two Years Following Graduation. Selection and placement, which this paper considers, are steps which precede training and development; and one phase of this broader problem is of immediate interest. As we all know, there is a large turnover in employment during the first two years after graduation, which means a considerable waste both for industry and for the individual. Some of the cost involved, of course, may be credited to valuable experience by the individual or charged to the expense of selection by the industry. Even assuming correct analysis in the original selection and placement such waste may still occur and the fact that it does is a serious failure on the part of both industry and the college graduate.

There is an explanation for the restlessness and apparent impatience of the college man, who is receiving his introduction to industry, which is not the conventional one that he is unwilling to undergo the hard training which business requires or that he expects to be made a general manager within the first year. Such attitudes may be symptoms but one main cause of the restlessness and dissatisfaction of so many college graduates which leads in the first year or two to severance of employment, voluntary or otherwise, is inherent in the college training and the better that training the greater may be the dissatisfaction.

Those who tend to become technical experts in industry are usually high in their instinct of workmanship, next in ambition, and least in economic motive.

During his junior and senior year the college man studies courses in economics, psychology, philosophy, or science and mathematics, which require

of him, as a rule, severe mental effort. He has been working on a high intellectual level. Then he enters the world of business and industry and the things which, for the first year or two at least, he must learn are matters of organization routine, locations, familiarity with stocks, lists of customers, methods of accounting and the like, all matters which can be learned by a man of high school education or even less. In general he has no task which is on as high an intellectual level as that on which he has been working in college. He has important information to acquire; but very little of the thinking, which is required of him, is of the same difficulty and continuity. Can we always blame him if he develops impatience and feels that the tasks on which he is engaged are below his mental abilities?

The worst of the situation is that he comes unconsciously to the conclusion that business and industry do not demand continued effort on as high intellectual level as did his college work. Of course he is given no task of this level until he has acquired the background of company experience and informational knowledge. The result, in general, is that his habit of study is interrupted, never to be regained, and that is why in the man specifications previously stated insistence has been placed upon the habit of study. Only the man who has the habit of study will, as a rule, ride through the early years of his industrial connection without a permanent lowering of the possible level of his intellectual effort. The result of such a lowering is that when, in the course of advancement because of his business acumen, human adaptability, and experience, the college graduate reaches finally a position where he is confronted with problems demanding intensive study on a high intellectual level, he is out of the habit of study. Then he is incapable of adequately attacking these problems; and instead of obtaining the solutions by scientific methods, he is guided by hunches, by so-called business judgment, and by conscious or unconscious imitations of the practices and methods of others.

Lack of Intellectual Growth. The failure of the college man to continue to grow intellectually during his early years in business, and the failure of business to provide facilities for such development, is the most serious failure in connection with the introduction of college men to business. In the case of those few men who have firmly acquired habits of study it will naturally be avoided, but in the case of those with weaker habits the failure can only be prevented if industry will provide facilities and guidance for the continuation of really hard study on the part of their college employees.

Summary. At our present stage of psychological development an interview method—a "method of free association" should be used. Six qualities are sought: intellectual curiosity, the ability to study, the habit of study, the ability to learn from men, an ability to cooperate with men, and last, a promise of the ability to lead men. One should attempt to find what are the applicant's innate tendencies and to get past preferences which are prejudicial and get at his fundamental aptitudes. One should then try to determine whether or not the student has the intellectual ability to deliver along the line of those aptitudes, and finally, whether he has the character and the personality, which is merely the expression of character, and the physical qualifications which will permit him to work successfully along those lines.

COLLEGE WOMEN IN BUSINESS

BY LOUISE MOORE, *Manager, Employment Department, Donnelly Garment Company*

Modern business executives, particularly in well-established organizations, are willing to make rather extensive use of college men. But about the value of college-trained women many of the same executives hold grave doubts. The number of such women in any one organization has so far been relatively small, and employers have frankly not known how to use them to the best advantage. These executives are sincerely interested in developing this type of worker, a fact proved by the generous response made by company members of the American Management Association to an informal questionnaire sent out in the course of an inquiry. Their comments varied from "I do not feel that a college education is a handicap to a girl planning to enter the business world" to a detailed account of the substantial contribution made by college-trained women employees. Women in business responded with equal generosity to letters of inquiry concerning their work since leaving college. In general, the problem of college women in business is one about which there exists more feeling than fact discovered after dispassionate investigation.

Summary of Response to Questionnaire.¹ The facts developed by the correspondence and by conversations with employers and employed women may be summarized as follows:

A considerable number of college women have deliberately chosen business as a career during the past twenty years. While employers are willing to make use of these workers they have not learned how best to select them and give them the elementary training on the job which they must have. Moreover, they do not know how to interest the college employees in their jobs, or how to use their college education to the best advantage. When employers are inclined to give the women more responsibilities, they are deterred by the probability of their finally marrying and leaving business. Business as organized at present offers to women little chance for advancement to positions of large responsibility. Executives realize that they cannot under these circumstances satisfy and hold the college woman of unusual ability and ambition.

On the other hand, the college women, while expecting to serve an apprenticeship in business, dislike routine work which makes no use of their four years of intense mental training. Many of them demand, sometimes with conspicuous lack of understanding of business problems, a larger responsibility than they have earned. They feel the unfairness of being denied the systematic business training accorded college men of mental capacity not superior to their own, and they resent the fact that their progress is limited by the custom of the organization. As a consequence of the lack of encouragement and of opportunity these college women sometimes fail to give to their employers the best results of which they are capable.

¹ As of Feb. 16, 1927.

Statistics of the number of college women in business are incomplete. Alumnae records of Bryn Mawr, Smith, Vassar, Wellesley, and Mount Holyoke indicate that an average of about 4.2 per cent of former students and graduates about whom data are available have entered business pursuits. This includes those in clerical and secretarial positions.¹ Probably a large number of women from universities and from other colleges have chosen such careers.

Most of these women have deliberately selected business since college graduates can choose among more occupations than can those who have not gone so far in school. Other occupations offer larger initial salaries and often shorter hours and longer vacations. The reasons for choosing business are sometimes Utopian. During the World War an acquaintance of mine was besieged by wild-eyed young college women demanding industrial executive positions. "Why," she wearily asked one enthusiast, "do you want to go into industry?" "To settle the controversy between capital and labor" was the emphatic reply.

The career of business, admittedly one of the most attractive for men of our generation in interest, and often in rewards, will be chosen by an increasingly large number of women with college training. It will at least be proportionate to the number in college. Very soon the "bright high school girl" so much in demand by employers at present will be supplanted by the "bright college girl." Indeed, one employer remarked rather ruefully that soon he will be obliged to hire college women whether he wants them or not, because all the desirable girls will have gone to college.

Our inquiry proved that the use of college women by business organizations is general, but the experience of most firms is limited. Answers were received from organizations of various sizes, among them some of the largest employers of labor in this country, situated in many different states, engaged in almost every sort of service, and in the production and distribution of a great variety of products. Their experience may be considered indicative of the experience of many other employers. About one-fourth of the company members of the American Management Association who answered the questions said that they had never employed any college women. These represented railroads, manufacturers of steel and of tools, of electrical apparatus, food, paper, and office appliances. About 15 per cent reported very limited experience. These were chiefly public utilities, machinery, textiles, and printing.

The most extensive use of college women was described by insurance companies, department stores, and manufacturers of various products. No uniformity of practice could be found to exist in the employment of college women by firms doing the same kind of work, since some have experimented much more widely than others.

Positions Filled by College Women. College women do a great variety of work. A number own and operate businesses built up by themselves, or

¹ Bryn Mawr, 0.8 per cent; Smith, 2 per cent; Vassar, 5.6 per cent; Wellesley, 6.5 per cent; Mount Holyoke, 6.1 per cent. A composite of available statistics not always from the same year, and certainly not based on the same occupational classifications.

inherited. A few officials of banks and of public utilities are college-trained women. Among the positions filled by employed college women the ones most frequently mentioned were librarian, dietitian, domestic science advisor, stenographer, file clerk, secretary, office department supervisor, assistant personnel director, assistant buyer, assistant in planning department, head of educational department. Production work in industry, where such enormous changes have been made during the past few years, and the whole field of selling, except department store selling, and some selling of securities had occupied few college women. Practically all of the situations reported lay in the field of what business men call "number two" positions, not in the line of executive responsibility, nor that leadership which undergraduates are so earnestly besought by college lecturers to assume in order to repay the public for the expense of their education. While many women successfully supervise groups of women workers, and even groups composed of women and younger men, few have charge of considerable numbers of men. Men do not like to take directions from a woman, and it is not the custom in the community to arrange matters that way, sums up the general feeling. Also, the employers think the public does not care to consult women in important matters, such as investment of large sums. Hence their use in banks doing a general business must be confined to certain departments where they do not meet the public. Twenty-nine firms answered definitely that women were not considered eligible for executive positions, while nineteen firms stated that women who were capable could receive such responsibilities. One manager said that they would not keep a college woman whom they could not rapidly advance.

Capability in Filling Responsible Positions. Lack of experience over a long period was given in some cases as the reason why college women have not been able to assume larger responsibilities. We have no data to prove what women can do if given proper training and encouragement, if they enter business in large enough numbers and remain long enough to fill many subordinate positions which will give them experience as executives. Also, we have no information as to the results of removing all prejudices against them as business workers. "Women are up against a velvet wall of prejudice, erected by men who on the surface are most cordial in their acceptance of women as fellow workers," was the summary of a man who has many opportunities for observation.

We may safely leave to the future the question of women in the highest executive positions. If the college woman can enter business and make moderate advancement, she will be obliged to be satisfied in this generation, which is necessarily doing pioneer work.

Lower Training Costs. An employer should find in the college graduate today a woman who has passed successfully all the preliminary intelligence tests, and has had the background of education which many large corporations are glad to give employees at company expense. "We have computed our training costs," said one, "against our returns for their services while they are with us, and we find that it is a paying proposition, and expect to continue using this source in employing correspondents." "We want the most training for our pay-roll dollar, and this we get from the college graduate," said another.

The list of assets of a girl just graduated from college reads about as follows: Some grasp of facts and some knowledge of where additional facts can be found; ability to study; an open mind; a fairly impersonal viewpoint; and some social graces. This list, made by employers, omits the personal satisfaction in the college experience that the graduate has as a permanent possession. But, as one woman said, one's personal satisfaction does not bring large returns in the marts of trade.

Employers' Objections to College Women. Perhaps because she does bring to her work a good deal of potential power, the employer expects of a college woman too much in the way of application of her knowledge to new problems, and an interest in a job which is useful but inspiring only because it is part of a much larger whole. He also expects a good deal of instant adaptation to a totally new world where the usual question put to the proposer of an idea is, Will it work? Does it pay?

Employers have summarized the reasons for the rather frequent failure of college women whom they have employed to fit into the business world as uncertainty of tenure, restlessness, inability of the worker to fit into her environment, impatient attitude toward the routine of work and toward business associates, lack of imagination, lack of training for business. These same complaints are made of college men; but college women suffer under the handicap of being women. Even after considerable experience many employers feel that they know very little about their women employees.

The employers do not share the old-fashioned idea that no one wants to marry a college woman. The danger of college women's marriage seems to be ever present in the employers' mind. College women may remain a shorter time in business than other women, because they enter at a more advanced age. The threat becomes less menacing after five years. Employers take the resignation of men employees with five years' service with some equanimity, feeling that the cost of training has been met by the services rendered. This is probably true in many cases of college women also.

Restlessness seems to be a chronic malady of college women in business and may arise from various causes. The first is, that the graduate may not have chosen her vocation honestly and intelligently. After a little experience some vocationally unadjusted women become, as one employer put it, "uncertain in their own minds as to what the final benefit of devoting a life to business service will be." We who do hiring know that most people waste years in finding out what work they can do best. The efforts at vocational counselling now made at most colleges should help in proper selection, particularly if colleges make an effort to discover business needs as well as the desires of the students. Employers will be obliged to sift out misplaced college women as they sift other employees.

Failure of Employers to Outline a Job Clearly. Much of the restlessness which employers complain of among college women is due to a failure of those in personnel positions clearly to outline the job, its agreeable and disagreeable features, its future and the means by which advancement can be made. Periodical conferences on progress help college employees as they do other workers. Furthermore, some restlessness is a sign of mental activity, and expected of young men. "I never held a job over six months until I was

about twenty-five years old," remarked a successful business man, "and I worked all over the United States." Women are as restless as men, but convention ties them more to one location until they begin to earn their own money. A number of business executives admitted that the reason why many of their college women employees had been restless was that the organization offered them no real chance to advance. "Men would be just as restless under the same circumstances," several of them wrote.

Unsatisfactory environment may cause restlessness. A college woman, used to a certain amount of social life with persons of her general training and tastes, may find herself in a small community with fixed social conventions and cleavages which do not permit her to have any standing. If it is no one's business in the organization to see that she meets congenial associates, she will soon leave a good job to return to a city where she can have friends.

Some college women who are not restless fail because of their attitude toward their work and their associates. While wanting to do big things they fail to study the intricate organization of their own business, and dislike the routine tasks which at first constitute their only possible contribution to the work of the firm. They want promotion as soon as they have mastered a task, when the task is what they are hired to do. They fail too often to see that they are employed primarily to assist, and that their employers are very little interested in their own ambitions for personal progress.

Cooperation with Other Workers. A snobbish attitude toward other workers is too often the outgrowth of the college woman's determination to make her beginner's job a stepping-stone to more congenial work. The morale of a department is considered by an employer of more value than the services of any individual employee. Failure to cooperate with others is a charge brought very often against the college graduate. College training should tend toward democracy, and usually does. Intellectual snobbery does not survive long, particularly if the organization contains any college people of longer experience who can help the new worker adjust herself. Those of us who try to settle differences in departments know that an attitude of lofty disdain toward fellow workers is all too common among grammar school graduates, as well as among college women. Occasionally the charge of snobbishness arises because the young college-bred employee, trained in self-control, seems to the other workers cold and unsympathetic, when her only fault is that she is not accustomed to speak the language of her new world.

Rigorous Discipline of Business. Employers complained also that college women who enter the business world decline to adapt themselves to the long hours, incessant demands, short holidays, and rigorous discipline demanded for success, or even for survival. This is probably caused not so much by laziness as by a feeling of revolt against subordination of self to the requirements of a ruthless and impersonal master through an endless series of years. Most mature men have forgotten their early rebellion at the stern discipline of business because it began when they were young and generally rebellious. College women, and college men too, have enjoyed leisure up to maturity, and their struggles at adaptation are regarded with the greatest surprise by the seasoned worker. Work during vacations is highly recommended as a preventive of this unfortunate condition.

Intelligence and Health. Among the complaints made, two were conspicuous by their absence. When women first began to demand college education numerous pages were written to prove that they had not the intellect to acquire such learning, and if a few did possess this unladylike amount of brains their health would be shattered by their studies. It is significant that no employer expressed any doubt that college women had the amount of intelligence he required, and no one said anything about delicate health of these employees.

Training on the Job. College women in business feel that some consideration is also due to their point of view. They are willing to accept the universe, but hope to work some changes in their relationship to it. They hope in time that they will be given as much training on the job as an intelligent man receives. Without some of this training they cannot progress far. Several letters from employers stated that, while men of promise are given a systematic experience in the organization and training in various branches, no women are so taught. Another large corporation advances to executive positions only persons with engineering training and experience. An official of this corporation, in mentioning specific work on which women had been employed, stated that a number of college women had applied for engineering jobs. "But we employ no women on this kind of work," was his conclusion. It is reasonable to suppose that some executive and technical capacity is latent in the large group of employed college women, and that training will make them more valuable to the company for which they work.

It is not only formal training on the job which women lack. They cannot learn from casual acquaintances as men do, on smoking cars, in hotel lobbies and at lunch. The talk runs much to "shop" on such occasions; men pick up business acquaintances and learn about trade conditions. Conventions close such sources of information to women. A friend of mine once remarked that she was glad when her hair turned grey, because then certain social conventions were waived and she could cultivate casual acquaintances without social censure.

Question of Remuneration. Salary demands made by totally inexperienced college women caused some comment by employers. Occasionally these complaints are justified. But in some cases the demands are probably not very insistent and are based on ignorance of the current wage of the job in question. One young graduate, many years ago, when she applied for her first job was asked what salary she expected. "A thousand dollars a year" was her immediate response. The interviewer must have been a person of discernment, for his reply was, "No doubt you can get that much somewhere, but the wages in this community do not run so high." The position which the graduate gladly took paid \$495.

College women in business hope that in time they can not only be given opportunities to learn more about their work in its large aspect, but that they can progress further in this work than they can now. Many of them believe they could successfully undertake larger responsibilities. A considerable number believe also that serious inequalities in salary could well be eliminated. Remuneration is still largely a matter of tradition, the state of the labor market, and the power of individual bargaining. Women have not on the

whole any advantage arising from tradition, or from the labor market, or from bargaining ability. The sooner college women cease to expect that salaries automatically regulate themselves the happier they will be.

Competition with Men. Employed college women believe that they meet with undue competition in their working life. In business, except in the routine work, they are competing in a man's world. They must count on the opposition they meet as competitors, as well as the opposition they face as a new force entering a crowded field. While women need not use the same tactics as men in this competition, they should clearly see the forces they are contending with and be dispassionate in judging their powers and planning their strategy. Men are accustomed to work with men. They naturally think of them rather than of a woman worker when a promotion is to be made, unless the woman has brought herself to the attention of the powers that rule by conspicuous service of some sort. Besides, in the competitive world where so many variables are to be reckoned with, it is not strange if men are unwilling voluntarily to introduce in high executive councils the "incalculable feminine viewpoint."

The employers' and the college women employees' point of view should both be considered by the personnel department. The college woman, like the college man, must be properly selected, placed and trained. Both are actuated by the same motives: desire for economic success, ambition to receive acclaim and credit, an instinct for workmanship—these motives varying in degree with each individual. The positions at present open to college women differ greatly from those open to college men. The kinds of advancement open vary still more. College men are usually expected to become, in time, technical experts or supervisors of important divisions of an organization, or executives of even higher rank. Business concerns have up to this time provided limited fields for success of women, whether college-trained or not. Consequently the training in less responsible work has been given to men who are to advance, rather than to women.

Good personnel practice demands that study be made of positions on which college women can probably succeed in making substantial contributions to the business, both at the present time and in the future. There should be no glossing over the facts as to present and future policies of the organization with regard to women's advancement. Even if the field for advance is limited, college women can be shown that there is joy in doing an excellent job with imagination and enthusiasm, and that this pride in work is at least one way of winning more substantial individual and group recognition.

How the Colleges Could Help. Colleges also could help if they would consent to recognize the world which their students must enter after graduation. Isolation from the hard realities of life is considered to be great at men's colleges; it is almost complete in most women's colleges. College faculties must be selected for their intellectual equipment and teaching ability. Some experience in business life would be an additional help, especially to women instructors whose contact with ordinary community enterprises, bitter industrial conditions, and the ungrammatical but shrewd office or factory worker is non-existent now. If college faculties realized how hard their graduates must struggle to adapt their carefully phrased

theories to the concrete facts of existence, they might care to give a practical slant to some of their lectures, showing how theories are applicable to the common task.

Business Needs Broader Knowledge of College-trained People. Business is itself changing, certainly in ethics, probably in its demands on employees. As organizations become larger and meet with more competition they need more variety of intelligence, a broader knowledge than can conveniently be gained from experience alone. The success of the schools of business administration is proof of this realization by men in business. Women are admitted to some of these schools. In the changing world of business women must be prepared to take a larger part.

CHAPTER IV

JOB ANALYSIS FOR POSITION CLASSIFICATION

CLASSIFICATION AND COMPENSATION PLANS AS TOOLS IN PERSONNEL ADMINISTRATION

BY E. O. GRIFFENHAGEN, *Senior Partner, Griffenhagen & Associates, Ltd.*

Personnel Administration Defined. Personnel administration is used in this connection to include the processes of formulating policies, and exercising managerial functions, respecting the selection, compensation, well-being, and conduct of the persons making up the human organization of an enterprise.

The only other phrases that have gained any vogue at all for this branch of management are "employment management" and "industrial relations." It is felt that the term "personnel administration" is the best. The term employment has a narrow meaning as well as a broad one and this leads to confusion. Similarly, the term management is somewhat more restricted in its significance, implying the exercise of executive functions whereas policy-making functions are very largely involved. The term industrial relations does not at all convey the idea, although it is appropriate as a name for the larger aspects of the problem of relationships between the workers as a group on one side and the proprietary and managerial interests on the other. Problems of industrial relations in this sense are often handled by the same department as that charged with personnel administration and what name should be given to the department is a matter that can well be left for local choice.

It is to be noted that the word "tools" is used. This has been done intentionally to emphasize the idea that classification and compensation plans in themselves are of no importance and that, regardless of the academic interest that they might hold for some, they would not warrant consideration by a group interested in management problems if it were not clear that they constitute definite, practical instruments for, and aids to, the handling of the important and intricate operations that go to make up that whole phase of administration that has been termed personnel administration.

Analysis of Classification and Compensation Plans. A classification plan for a service is the plan which, after due investigation and analysis and the preparation of "position descriptions," (1) groups the positions making up the service into "classes," each with a distinctive "class title," according to the similarity of their distinguishing characteristics such as the duties and responsibilities involved and the qualifications required of their incumbents; (2) specifies the nature and requirements of each class or group of positions thus recognized in "class specifications"; and (3) records the rules, regulations, and practices respecting positions and their incumbents thus classified.

It is evident that the classification plan as described is not a simple thing. Further, this statement incidentally defines many other important terms: position description, class specifications, and "class title." It shows clearly that a classification plan is made up of a number of parts. In the first place it is a record of a schematic arrangement of positions making up the service with primary reference to those attributes that really determine what the position is, namely, the work involved. This part may be referred to as the "classification outline." It also includes a set of descriptive statements and a record of standards for the several classes of positions established. These same statements are convenient places in which to record various other rulings that relate in common to all positions found within the classes described. The record in its complete form is referred to by the term class specifications. The term "occupational specifications" may be preferred. The third element in the classification plan under this definition embraces those general rules of application and administration that are necessary to govern it. To recapitulate, the classification plan comprises:

1. A schematic arrangement or classification outline by which the positions in the service are grouped into classes. The analysis of duties and the writing of position descriptions are considered as prerequisites.
2. A set of class specifications, and
3. A code of "classification rules" for purposes of application and administration.

The word *class* has been used for a definite concept, namely, for the idea of a group of positions sufficiently alike with regard to those attributes of vital importance from the standpoint of personnel administration, such as duties, responsibilities, and qualification requirements, to make them properly subject to common treatment in the processes of selection and compensation as well as related employment operations.

This concept is indispensable and must be recognized regardless of the term applied to it.

Other Names in Current Use. We do not find anything in the general literature of personnel administration that names, expresses, or attempts to express the whole idea of a classification plan as it has just been outlined. The notable exception is found in the public service where these various principles were pretty clearly recognized as far back as 1919 and have been rather thoroughly written up from time to time since then. But we do find in the business and industrial world such words as "job analysis," "occupational description," and "job grading." At times these are used very broadly, at times very narrowly; sometimes they mean a process, sometimes a written record, sometimes a policy. The first two of these phrases are nearly interchangeable. In some uses they correspond roughly to the term class specifications (or occupational specifications) as just defined and in other applications they are used to mean a "position description." Although it is admitted that their present loose use makes any more definite use hereafter improbable it is probably incumbent upon the writer to attempt to indicate a desirable restriction in their application.

Take job analysis first. There is no objection to it as an informal way of referring to the *process* of ascertaining and examining duties and the other

attributes that go to define a given position but it is believed that the more exact term position description is better for use in referring to the record that is made of the findings of such an examination.

Defining the Word "Job." The word job in this expression is not good for scientific purposes because of its ambiguity. A job may mean a specific assignment to an individual that makes up only a small part of the sum total of his work, or on the other hand it may mean a very large project calling for the attention of a considerable force of men. In a dictionary sense a job is an odd or occasional piece of work. It is true that it is used as an informal or semislang word for situation or place of employment but it is doubtful whether its use because of this is really an advantage.

The word position fits what we are discussing perfectly. It is definite, dignified, and entirely appropriate. It is hereby accepted for use in these remarks and recommended for general adoption where reference is to the idea of an office, a place of employment, a post, or a group of duties calling for the attention of some one individual for their proper performance. The idea of a position should be held up as something distinct and apart from an employee. That is not at all to say that the incumbent does not often influence the nature of the position, but it means that the concept of a position should be of things to be done rather than of the doer.

Application of Job Analysis. As has been said above, job analysis is sometimes used for a process, sometimes for the description of a position, and sometimes for the specifications of a type of position. It has been recommended that it apply to a process—nothing else. The word analysis immediately brings to mind the taking apart of a thing, its solution into constituent parts, or elements, and their examination. It should not be used to mean a plan, a record, or a statement, even though it may be grammatically proper to refer to the record of the findings of an analysis as the analysis.

The term occupational description has had some use and is advocated in a well-known treatise on personnel management largely because of the first objection raised above to the word job. But occupation is also somewhat ambiguous; it sometimes refers to a specific position but more often to a vocation or line of work. As a synonym for the term position description, occupational description is for this latter reason not good. As the synonym for the term class specifications it could well be considered. In fact the term occupational specifications has been advanced as an alternative to class specifications in these remarks. But the word specifications is believed much better than description because it carries the idea of a standard, of something to be demanded. Also there is a practical advantage in using it if we use the word description for our record of what we learn about an individual position.

Definitions of Compensation Terms. A compensation plan for a service is a plan by which positions as arranged under the classification plan are evaluated in relation to one another, scales of pay (either absolute or relative) are specified for each class of positions, and established policies, practices, and rulings regarding the compensation and changes in compensation of positions and their incumbents are recorded. The compensation plan is made up of a number of more or less distinct parts:

1. The "compensation schedule"—the structure of the value relationships among the classes of positions (either in terms of money or terms of other units that will record relationships and that can be translated into money value).

2. The "scales of pay."

3. The code of "compensation rules" for purposes of application and administration.

There has been so little put on record with regard to the development of compensation plans in this complete sense that there is no need to pause long to discuss terms or definitions. The expression that is most commonly used in referring to this general aspect of personnel administration is "salary standardization." It is felt that the word "salary" is no better, if as good, as the word "wage" and that the word compensation inasmuch as it embraces them both and includes certain other elements that cannot be disregarded, such as allowances of various kinds, is preferable to either. There are strong objections in the writer's opinion to the word "standardization" in this phrase. It implies a certain inflexibility that it is not at all desirable to imply. It also implies that the absolute pay is standardized whereas the thing that should be standardized is the relationships in pay. The term, like the term job analysis, has one good use, however, in that it can be applied to the name of a process and in that use may be more popular than a wordy expression such as "the preparation of a compensation plan." But that is a very poor reason for its adoption in any scheme of scientific terminology.

Perhaps mention should be made of the term "job grading" as it has been used. The objections to job as against position, just stated, stand. When positions are classified, the classes can then be graded or ranked. In other words, the process of classifying includes the idea of grading.

Uses of a Classification Plan, Its Place in Personnel Administration. The first need for a classification plan is in connection with the primary employment function of *selection or hiring*. Unless those charged with the securing of the individuals best fitted for the work that the enterprise needs to have done, have a clear understanding, reduced to a complete, usable statement of what that work is, how can they proceed effectively? Nor is it sufficient that they should be able to get the facts with respect to any particular position at the time it is to be filled. It is not practicable to carry in mind or to carry on record a sufficiently complete statement of the duties and requirements of thousands and thousands of individual positions or even of hundreds and hundreds and to devise special tests or even bases for personnel judgment on short notice with respect to each one of these. Those positions that call for the same qualifications ought to be grouped together and the qualifications that they call for ought to be scheduled and specified, the specifications ought to be continually improved upon, and methods of selection ought to be perfected with reference to them. Applications of candidates for employment ought to be related to these classes of positions. As new positions are added to the organization, their places in the classification should be noted and, of course, existing positions should all be tabbed to show just exactly where they belong. The use of classification titles will, of course, do this readily. The practice of using these same titles in all employment negotia-

tions, all interdepartmental communications, throughout the pay-roll procedure, and in budget records, will follow as a natural result. The first use for classification, therefore, is in aiding the recruiting of the service, and an auxiliary use is in standardizing employment nomenclature.

Another use, probably just as important as the first named, is to afford a basis for the development of an equitable and uniform *compensation plan*. The first consideration in determining the proper pay to be offered for any position in an organization is obviously the nature of the position. Before any one occupies it there can be no other basis. It is of the very essence of an equitable compensation plan that the relationships between the scales of pay prescribed for the several kinds of positions should be correct; difficult work, responsible work, important work, being compensated in such a way as to attract those who prove their fitness to handle it. It would be manifestly impracticable in a large organization to attempt to set up, in terms of differences in the pay scales, those minor variations that exist between positions of substantially the same class. The whole problem of devising a compensation plan is brought within the bounds of possibility by dealing with positions in groups, each group or class including all positions that are properly subject to common treatment. But the classification plan has already done this, and it serves a very useful purpose in this connection.

Still another use of the classification plan is to provide a place and a method for the recording of the rules and practices of the service with respect to the various kinds of employment and types of positions that constitute it. The class specification, for example, can be expanded to include much more than the statement of general duties and of required qualifications.

The Process of Classification. The service of any enterprise that calls for the joint effort of a number of workers may be said to comprise a number of positions having an organization relationship to one another, that is, grouped into departments or divisions and arranged in established lines of authority. Each of these positions calls for the performance of certain duties, the carrying of certain responsibilities, and in most cases, the exercise of at least a degree of authority. The nature of these duties and the magnitude of the responsibility and authority, together with the departmental and other environment, determine what qualifications the incumbents must possess. Where it is difficult to describe the common characteristics of a group of positions that are to be allocated to the same class in the process of classification, it is often possible to adopt the expedient of explaining the kind of ability, kind of experience, kind of skill, etc., that a person qualified to handle the work must possess.

The first step in the process of classification is, therefore, to learn all that it is practicable to learn regarding the duties of each position in the service. The term job analysis, if it is to persist, ought to be restricted to this process. A rather elaborate technique has been built up and perfected in this work by those who have been engaged in it professionally, and there is at least partial record of it in certain places. There is no space available to go into it here.

When the examinations have been completed and the position descriptions written, the actual work of classifying may be undertaken. Following

the common sense method that should be adopted in any classification process, it is desirable to recognize first broad general divisions and then smaller groups until the smallest working unit is reached. This is the class—a group of positions that may to all intents and purposes be considered interchangeable. In many cases each position will constitute a class in itself. Almost all higher and supervisory positions fall into such “one-position classes.” The broad general groupings may be both according to line of work and according to importance of work.

The major features of the complete classification plan that will result from this program will include:

1. A classification outline or schematic arrangement which will set up the broad occupational divisions, and under them the narrower occupational groups and the individual classes of positions, arranged according to series of classes, coming within each occupational group.
2. The class specifications (or occupational specifications) each to show:
 - a. The adopted class title to be applied to the class and to all positions in the class.
 - b. A general description of the duties common to all positions of the class supported by typical tasks as illustrating kinds of work falling within the general description, chosen from actual cases, to support and amplify the general duties statement.
 - c. An enumeration of qualifications required, which may be grouped into two parts—necessary qualifications and desirable additional qualifications.
 - d. Notes regarding lines of promotion, preferably in the form of a schedule of positions considered next higher in rank, and positions considered next lower in rank.
 - e. Notes regarding compensation if there is a compensation plan in effect. This, of course, is the place where the scale of pay for this class of positions should be recorded.
 - f. Any other facts, rulings, or memoranda that relate to the class and that have a bearing on administrative processes in personnel matters.
3. The rules of administration presenting clearly and in logical order, the principles and methods by which the classification plan is to be devised, adopted, applied, and amended; by which new and changed positions are to find their places under the classification outline; by which specifications are to be constructed, employed, and perfected; and by which employment processes are to be controlled or related to this basic plan and its scheme of nomenclature.

Further Notes on Classification Technique. Some further discussion of the problems and processes of classification technique may be of interest to some, although probably only to those who have the actual classifying work to do. The primary classification may be both vertical and horizontal; the horizontal scale representing the general line of work or occupation, and the vertical indicating the importance. The broadest column is often called a “service” and the next subdivision or subcolumn the “occupational group.” Next we come to a number of classes that are closely related, being differentiated only by rank. We call this division a “series of classes” and finally we come to the class itself which includes all positions that are substantially alike.

The vertical differentiation is substantially a differentiation on the grounds of importance or rank or supervisory authority. It is impracticable to draw straight parallel lines throughout the service on such a basis, however.

Characteristics of Positions. The attributes of positions—much like those of persons—are manifold, and the relationships between them which might be recognized in a classification scheme are bound to be numerous and complex, although it is true that they are of two general types—similarity in *kind* of work and similarity in *rank* of work.

This suggests the possibility of using a two-dimension chart as an aid in presenting some of the methods and terms used in the actual process of classifying. It is to be understood that the analogy between such a physical arrangement of areas and the mental grouping of abstractions is rather forced, but it may be helpful in illustrating a few ideas hard to convey otherwise. For reasons later given, a three-dimension model would be better if it were practicable to reproduce it. A word description of the layout will have to serve.

The horizontal scale of the illustrative chart would indicate the range in the *kind* of work involved, that is, it would attempt to represent the variation in the subject matter dealt with, in the types of skill and fields of knowledge required, and in the form of application of this skill and knowledge to this subject matter. Broad fields of service would be represented by wide columns erected on this horizontal scale; say, a column headed "clerical service" and flanked on the one side by one headed "accounting service" and on the other by one labeled "mechanical service." The divisions between these fields would be represented by vague and wavy lines. Narrower sub-columns would illustrate the occupational groups, the "general clerical," for example, with the "office appliance operating" shading off to the right and the "accounting clerical," to the left. The common clerical "series of classes," junior clerk, senior clerk, principal clerk, would occupy the middle of the general clerical group column—and each level in this subcolumn, namely, the junior portion, the senior portion, etc., would also be separated from the next by the same kind of hazy band or twilight zone to illustrate the absence of any sharp or hard and fast distinction.

The vertical scale of this chart—as will already have become obvious from the foregoing illustration of the clerical series—is a scale on which the range in the *rank* of the work would be indicated. It would attempt to represent the variation in importance, difficulty, responsibility, authority, and those other factors that usually determine rank.

The positions themselves—if we carry this analogy to a logical conclusion—would take the form of areas of divers sizes and shapes. The vertical dimension will represent the range in importance from the "duty" of lowest rank to that of the highest. The horizontal dimension will indicate the range in kind of work involved. Some of these areas would be charted as falling clearly in the central portion of one of the rectangular spaces representing a class. Others would jut from one class into the one next to it—for example, one might overlap the boundaries of the senior clerk and senior account clerk classes because partaking in a measure of the nature of each. Another might lie in part in a "senior" rank although the greater part of its area may be in the "junior" space just below.

The Process of Preparing a Compensation Plan. The work of devising a compensation plan calls for the use of all of the data collected and employed in preparing the classification plan and the supplying of the one additional element of evaluation. This evaluation must first be relative. It must take into account other classes of positions. It must also be relative as it relates to the value of the service of the employee upon appointment as compared to that of his service after he has become thoroughly familiar with, and experienced in, the work. In addition to the element of evaluation, exceedingly complex questions of managerial policy need to be dealt with, relating, for example, to the basis of increases above the minimum or starting rate, the rate of increase, the times of increase, the amount of increase at one time, the enforcement of limits, the compensation adjustment in case of promotion in rank, etc.

Notes on Current Practice Respecting Classification Plans. Probably the best way of picturing recent progress with respect to the actual adoption of classification and compensation plans is to give the results of a recent canvass made of a number of large business enterprises of the more progressive type. This will give a picture of the status of the movement today that will be even more significant than any attempt to trace the history of the movement during recent years.

The concerns making up the "sample" are forty-eight in number. Lines of business in which office workers predominate are strongly represented. The average number of positions is around 5,000 (a total of 240,000). The average number of office positions (excluding technical desk positions) is 1,300 (or 26 per cent).

Of the forty-eight concerns included in the canvass, thirty-eight (or 79 per cent) apparently maintain a classification plan which has at least some of the essential elements as outlined in the foregoing discussion. Some refer to a classification plan giving compensation as the basis, but these are not included among the thirty-eight and should not be, because such a mere grading according to pay does not constitute a classification in the sense of the term as used in these remarks any more than a classification according to departmental location, hours, age of incumbents, or any such feature would.

In fifteen cases it is specifically stated that the plan applies to all positions in the organization, no occupations or departments being exempted, but in most cases only part of the service is embraced. In only two cases, however, is the clerical service excluded. The average number of positions covered is about 800, or 16 per cent of the total, but these last statistics should probably be considered as very unreliable because of the vagueness of the information as to just where the classification stops in each case.

In only eight cases is it claimed that the plans reported were used before 1920, and in three of these eight cases the plans were just being started at that time. However, most of those that have not yet installed anything along this line realize their need and are considering something of the kind at the present time.

On the fundamental question of the basis for the classification, this inventory of current practice showed a fairly general conformity with the principles enumerated in this paper. All of the thirty-eight concerns indicated

that their classification plans are based on either the duties of the positions or the qualifications required in incumbents or on both. Three said specifically that personal qualifications were the basis, while five took pains to point out that they paid no attention to personal qualifications but followed duties exclusively. Three companies that reported a grading scheme based on compensation have not, as has been said, been included at all. The remarks on the basis of classification brought out widely varying ideas as to the degree of refinement that is desirable. In some cases job analyses are apparently carried to a point where practically every position is made a separate class. In other cases very broad groupings are accepted as sufficient.

Standardization of Class Specifications. An attempt was made to ascertain the extent to which the form and content of class specifications or occupational descriptions have been standardized and it was very clearly brought out that there is nothing even approaching uniformity of practice in this respect. However, only seven out of the thirty-eight companies that claim to have classification plans admit that they do not maintain any specifications at all. But the specifications that are referred to are apparently of many degrees of completeness. Twenty-four concerns maintain a statement of duties applicable to the class as a whole. Some of these include enumerations of specific tasks. Ten of the thirty-one companies do not attempt to include specific examples of duties falling within the class. All but six concerns say that the specifications indicate the qualifications that incumbents should have, but in the actual statement of these qualifications there is every imaginable variety.

Promotions and Transfers. But few of the specifications throw any light on lines of promotion, although some seventeen concerns do indicate that they have set up promotional lines, at least in a general way, for their own guidance. Apparently promotions and transfers are customarily cared for as special matters involving individual judgment at the time. While it probably should be assumed that reference to essential records is made when this judgment is to be exercised, nevertheless the suspicion arises that the accident of departmental location and personal relations with those next higher in the line of supervision all too often might be the controlling factors.

The opinions of the companies as to the uses of job analyses, occupational descriptions, standard terminology, etc., as tools in the work of employment management, may be summarized by saying that thirteen mention "basis for selection," twenty-five mention "basis for compensation," and three mention "basis for budget control," and none mention "basis for standard terminology." Some mention "use in promotional schemes" but the evidence that such use is made is not convincing.

Notes on Current Practice Respecting Compensation Plans. Apparently action with respect to the development or recognition of more or less formal compensation plans is not so far along as in the case of classification. However, thirty of the forty-eight companies claim to maintain a schedule of fixed salary ranges in a written form. Of these all are said to be related to the classification plan in effect.

The elements recognised in the scales of pay included in the compensation plans reported upon are indicated by the following tabulation:

Rate	Companies
Minimum.....	33
Maximum.....	31
Intermediate.....	19

Written regulations, as such, are apparently not usually considered part of the plan. The practice in matters of administering the scales seems to be, however, that in allowing salary increases, time and merit are both considered by all companies except one which depends entirely upon seniority and one which allows only merit to decide all cases.

On the interesting question of whether the minimum rate is, or is not, always the starting rate, it is found that commonly the minimum rate is not adhered to for starting, but rather that the background of the applicant, including his education, age, existing outside rates, previous similar experience, exceptional qualities, etc., is allowed to alter the rate proportionally. This is true in all but twelve cases. Even in these cases, occasional exceptions are found for technical men, and for others under abnormal conditions.

SOME CONSIDERATIONS IN INSTALLING A SALARY ADMINISTRATION PLAN

BY E. H. LITTLE, *Assistant Supervisor of Industrial Relations, United States Rubber Company*

Why Do We Need a Salary Administration Plan? A survey of jobs upon which a job classification can be based looking to an organized plan of salary administration is not a day's, nor a week's, nor a month's job. If the clerical force numbers upwards of 500, involving more than 100 different jobs, a year is the least time upon which to plan. The doing of the job is a specialized piece of work making its own peculiar demands on the persons carrying it on. The first question then is, Is it worth doing? Will the returns justify the money expended?

Some of the conditions which have led to affirmative answers to those questions are:

1. Varying rates of pay for similar kinds of work.
2. Present salaries the result of seniority rather than difficulty of work performed.
3. Increases in salaries due to efficient self-salesmanship on the part of the employee, or to the selling ability of the department head rather than to improved performance or greater value to the company.
4. Material differences in standards of salaries in different departments, in other words, high and low paying departments frequently irrespective of the type of work done.
5. Resentment of department heads to promotions. If the jobs have not been analyzed, demonstrating the differences, the transaction savors of competition within the organization.
6. Irregularity in the practice of granting salary increases.

7. No plan of promotion enabling the employees to fit themselves for the higher positions where the higher salary should be in proportion to increased responsibilities.

8. Hiring of new employees at higher rates of pay than now being given to satisfactory workers on similar positions elsewhere in the organization.

By Whom Is Such a Plan Initiated? The first stimulus towards salary administration comes usually from one of the three following sources—from the employment department due to difficulties with hiring rates, transfers and promotions; from the treasurer's department, due to evident discrepancies in salary standards between departments; or from the person with final authority for granting or refusing salary increases. The greater his desire to be fair to the employee and to the company alike the more difficult does he find his task of giving equitable decisions on the basis of insufficient, unanalyzed and non-comparable data. The actual source of the impetus, however, is of minor importance compared to that of being assured that the chief executives are thoroughly convinced of the necessity for action before the initial steps are taken. This is the first essential and fundamental principle of a salary administration plan.

Outline of the Plan. At this point we are assuming that the chief executives have decided that a better method of salary administration is essential to the best interests of the company. They are then confronted with two distinct problems; first, what must be done; and secondly how to do it in their particular organization. In outline a salary administration plan divides itself into four distinct parts.

1. *Job analysis*, involving the collection of complete information regarding the duties of each position, and the qualifications necessary to satisfactory performance.

2. *Classification of positions*, involving the establishment of grades, each grade calling for approximately the same exercise of responsibility and job technique, and the classification of positions accordingly.

3. *Salary standards*, calling for the establishment of a minimum and maximum salary limit for each grade.

4. *Salary adjustments*, involving the working out of a standard procedure for analyzing new positions, reclassification of revised positions, and the considerations of salary adjustments on the basis of individual performance, and with regard to the established salary ranges for the respective grade.

Each step planned must be reviewed in the light of the following question: Is it calculated to promote greater cooperation and agreement on the part of the persons concerned? And that question must be considered individually by each company for each step taken. No specific formula will be applicable although one general principle is worth keeping in mind. Opportunity to participate is the first step in promoting the desire to cooperate.

Personnel of the Committee. Having outlined the steps in reaching our objective, we now come to the problems of initiating the undertaking. The chief executive or executives will undoubtedly appoint a committee. Its personnel deserves careful thought and real consideration. If the organization in question represents the growth and expansion of a single organization,

in all probability the authority for a wide diversity of functions will emanate from a single source. It will be sufficient for subordinates of all grades to know that "the V. P. is back of this." Under such circumstances the interests represented by the personnel of the committee are of secondary consideration. Under these simplified conditions, the committee will usually be found to be a working committee, selected for the ability and contribution each individual member can make. Desirable as this situation is, it has to be sacrificed under other conditions. Where the organization represents the amalgamation or consolidation of several companies, dividing lines and departmental walls are well defined and unyielding. Authority is widely decentralized and divisions are practically autonomous in themselves. Here the committee must be selected for their prestige with their particular subordinates. They will be men very much higher up in the organization than in the former case, and due to their greater responsibilities will have little time to devote to the details of the problem. They cannot be expected to do any of the real work. It must be their function merely to accept or reject the conclusions and formulated plans which are presented to them for consideration. Under such circumstances it might be advisable to have a second working committee, but this seems a bit cumbersome—unless it proved to be the natural outgrowth of circumstances.

In our own case the title of the committee has come in for quite definite consideration. In the beginning it was quite naturally called the salary standardization committee. Later when we found that the by-products covered a field so much larger than merely salary administration, we changed its title to the job analysis committee wishing we had made that decision originally. This is a bit of experience which we pass on for what it may be worth.

What Positions Are Included? An early decision is concerned with the scope of the plan, that is, how many of the positions will be included. It is advisable but sometimes not expedient to carry the study up to and including section or department heads. One company has described the extent of their undertaking, as excepting only the junior and senior executive officers. The guiding principle is this: To correctly appraise the higher clerical positions, it is essential to have all of the supervisory positions on which any of the actual clerical work of the section is actually performed. Without the knowledge of the functions of persons holding such positions, it is very difficult correctly to determine the degree of responsibility involved by the position in question.

Next, coming to the actual work involved; even if the committee's function is to "work" not "sell," at least 99 per cent of the work must be done outside the committee. Needless to say the *selection of the person or persons for this job* is vital to the success of the whole undertaking. And this raises another question: Shall one depend upon one's own organization or shall one look elsewhere among the many consultants available today for such work? Briefly I am lining up here the pros and cons of doing the job with a person from the local organization.

Arguments against Using Home Talent. 1. The job requires specialized analytical ability and a knowledge of office procedure. A person with such ability and knowledge may not be available.

2. There is a very definite technique of analyzing and classifying jobs which requires considerable experience to acquire proficiency. The local person has to learn while doing.

3. The local person has less prestige and will be subject to more questioning by department and section heads.

4. For the reasons given above it will probably take longer to complete the job.

Arguments in Favor of Home Talent. 1. In the course of doing the job much valuable knowledge is accumulated which is partially lost to the company if the work is done by an outsider. This is all the more pertinent if the work might be carried on by a member of the employment department. When such knowledge is the background upon which the employment department functions, the department heads feel that their problems are understood and appreciated.

2. A member of the local organization will have more means of feeling the pulse of the organization and will assume more responsibility for correcting situations which would interfere with the future success of the eventual plan.

3. The job is not complete with the analysis and classification. It must be carried on. New positions are created and duties change on old positions. If the major responsibility for the actual work has been carried on by a consultant, when he withdraws the plan may become the step-child among other more favored projects. Under such circumstances its future is questionable.

4. Considering the by-products which are yours if you do the job yourself, there can be no question that the cost element is all in favor of the home production.

How to Gather the Necessary Information. In this instance I shall outline our own method. The committee had decided upon asking each employee to fill in a questionnaire outlining his duties—regular, periodic, and special; and each department head to fill in a questionnaire for each position under his supervision. In this, the department head was asked to check type of duties, education, training, experience, and qualifications necessary to satisfactory performance, as well as to give the element of the job most difficult to learn.

In the name of the committee a letter was written to each department head outlining the proposed plan, the objectives to be sought, and the importance of their cooperation. To this was attached a copy of the department head's questionnaire, the employee's questionnaire, and a copy of the letter for each employee which the department head was to send out in his own name. It will be evident that our intention was to show at the start our dependence upon the participation of our department heads, and the importance of their contribution to the whole plan. We sent out all questionnaires at the same time, studied them on their return, department by department, interviewing the employee or supervisor when discrepancies were evident, wrote up a position description, roughly classified the position, and then studied similar positions irrespective of departmental lines. This briefly was our procedure for collecting the necessary data.

In our comparison with other companies, we have found quite different methods in use. A very general method has been to proceed department by department, asking only the employee to fill in a questionnaire, follow this up with a personal interview, write up a position description, check this with

department head, and then classify the position. The argument has been that the department heads were too busy to fill in questionnaires. The two methods may be equally good and it is for that reason that I have outlined them here. The choice between the two will probably depend upon local conditions, and the committee's opinion as to which method is best calculated to secure the participation of the department heads, that being the important point. In my own mind the personal interview with the employee is the most efficient way of actually collecting the necessary information about the position. It may not, however, prove to be the most practical means of securing the desired cooperation.

The "Position Description." On several occasions we have used the term position description. It may need explanation. With us it covers the following items:

- Title, department, etc.
- Educational requirements.
- Necessary experience, general and specific.
- General brief description of position.
- Type of duties.
- Rating of job.

The position description should include all the elements of the position by which its classification is determined, and it forms the basis of any discussions regarding the position either with the committee, the department head concerned, or the employee, as well as providing the employment department with a very useful tool for all its transactions. As such it is a vital cog in the wheel. Its value and usefulness depend at the same time upon its brevity, clarity and all-inclusiveness, a combination not easy of attainment.

Having collected and analyzed the necessary data regarding each position, the question now before us is:

How Are the Positions to Be Classified? And it is a crucial question. Upon its satisfactory solution depends the success of the whole plan. By some means these positions must be grouped so that like salary ranges for a given number of positions recommend themselves as the fair and equitable remuneration for the duties discharged. Following are three different methods being applied, usually in combination:

1. The departmental order-of-importance method. By this method the positions in each department are arranged in the accepted order of their importance. Departments are then coordinated, and dividing lines drawn between grades.

2. The grade description method. By this method definite grades are recognized and described and positions classified accordingly.

3. The job rating method. A scale is set up allowing a certain number of points for each element by which all positions are to be analyzed. The sum of the points judged to represent the requirements of a particular position results in an index showing the relative place of that position with respect to other positions. At this first mention of the job rating method, we wish to emphasize the fact that we are referring to the rating of the position itself, not to the person on the job.

In practically no instance that I know of was any one single method used to the exclusion of the other two. In general two methods have been used, one as a check against the other.

The order-of-importance method. This I shall not attempt to discuss, having had no experience with it.

The grade description method is dependent for its success on the definitions of the grades being simple, clear cut, and distinct each in themselves. Brief, concise descriptive terms are essential. If you expect to use these grade descriptions in asking the department heads to check your classification of their positions, their differences must be easy to grasp and to apply. It is true there will be positions on the border line, usually because they involve two distinct sets of duties of quite different character. In these instances, an arbitrary decision is almost inevitable. But on the basis of experience, I would say that clear cut distinctions between grades with some arbitrary decisions were preferable to elastic grade descriptions which were difficult to master and permitted of several interpretations. In deciding upon a suitable grade description, one can obtain very definite help by comparison with other companies who have been working on the problem. Our own grade descriptions are based on those developed by Marion A. Bills in her work for insurance companies, and published in the report of the Committee on Salary Standardization of the American Management Association.¹ Our revision was in favor of a more simplified form which to us seemed logical for the executive offices of an industrial concern compared with the inevitable subdivisions and refinements necessary to a large financial institution.

Following is a copy of the grade descriptions by which we have classified our positions:

A. Work of office- or messenger-boy character.

B. Simple operations. Use of a few definite rules. Routine operations performed under close supervision.

1. Simple clerical work requiring no experience; or training, but no experience, on simple machines, such as, sorting, key punch, ditto and adding machines.

2. Simple clerical work but requiring some experience to perform job satisfactorily.

3. Outside training but little experience on more difficult machines, such as, typewriter, non-listing calculators, multigraph, etc.

C. Requiring recognized clerical ability. Application of a large number of rules though definite and specific; or considerable experience on machines listed under B3.

1. Requiring recognized clerical ability, but the exercise of no definite responsibility, either because of the character of the work, or the closeness of the supervision.

2. Experienced operators on following machines; typewriter, non-listing calculators, bookkeeping and tabulating machines.

3. Work of C1 character but of more responsible nature.

D. Requiring complete and intensive knowledge of a restricted field.

1. As above.

2. Work of D grade plus supervisory responsibility of a minor character.

¹ See p. 863.

E. Requiring knowledge of general policies; command of general rules and principles with application to cases not previously covered and may require long experience with the company.

1. Work of the above character where experience is not necessarily long but must have been gained within the company.
2. Work of a more technical or more difficult character, but experience not necessarily within the company.
3. Work of *E1* grade plus supervisory responsibility.
4. Work of *E2* grade with long experience with the company. Or work of *D* grade which is not subject to check and therefore where the promotion of the employee on the job is generally undesirable.

F. Work of a highly technical or confidential nature or of semiexecutive supervisory character.

1. Highly technical or confidential work.
2. Semiexecutive and supervisory in character.

One advances the job rating method with a full knowledge of its limitations and dangers. On the other hand it has advantages so distinct that it cannot be lightly dismissed. There is no question but that it presents the correct approach to the problem. It is an invaluable aid to analysis, forcing the raters to consider each element of the position and to form and record the impressions of the importance of that element. That is the only objective, scientific method, in a field which in the past has been governed by only three factors—circumstance, opinion, and the law of supply and demand. And unfortunately some of our clerical positions are so specialized that they are wholly removed from that inexorable level-changing law, and opinion and circumstance have become the only criteria. The rating scale has two stumbling blocks: first, the choice, definition, and interpretation of the elements to be rated; and second, the allocation of the numerical points to each element.

At this point, I shall describe our own method of developing a rating scale and our estimation of its value to us.

First after considerable study, we determined upon the following elements to be rated:

General Education. Maximum points 6. The degree of general education, attained through school or individual study, necessary to give background for all-round performance in the position.

Special Training and Experience. Maximum points 8. The amount of training in special courses, and experience in previous positions required by position in question.

Special Knowledge. Maximum points 6. The amount of specialized knowledge of the functions of the department required to perform the work.

Accuracy and System. Maximum points 6. The necessity for accuracy in copying, posting, checking or machine operation, and the need for system and neatness in performance of work.

Ability to Plan, Execute, and Accept Responsibility. Maximum points 8. The extent to which position requires the ability to plan for self or others, to carry out policies, and to be responsible for results.

Supervisory Ability. Maximum points 4. The degree to which successful performance in the position requires the ability to direct others and to obtain their cooperation for the attainment of results.

Judgment. Maximum points 6. The degree to which position requires the exercise of discriminating judgment and the ability to arrive at logical conclusions.

Mental Ability. Maximum points 3. The mental alertness necessary to sense the significance of facts and situations or to grasp and remember a multitude of details.

Ability to Make Good Contacts. Maximum points 4. The extent to which position requires a personality which can make a prepossessing impression for the department or the company.

Integrity and Professional Ethics. Maximum points 4. Degree to which position requires a person whose integrity has been proved and whose discretion regarding people and things can be depended upon.

Evaluating in Money. In making use of this method of evaluating our positions we realized that no rating on our part would affect the salaries we were forced to pay on several different positions. Our old friend, the law of supply and demand, whose alias is the "current market rate," told us in no uncertain terms what we *had* to pay the office boy, various grades of typists, stenographers, comptometer operators, telephone operators, bookkeepers, tabulating machine operators, and so on, for about 32 different jobs. That was fact 1. Fact 2 was that we needed the rating to indicate correctly the approximate salary for our specialized U. S. Rubber jobs—order clerks, stock distribution clerks, financial analysis clerks—in other words, for clerical positions where the employee's value to us was in direct proportion to his knowledge of *our* particular business. And fact 3 was concerned with the office boy: What did he represent to us? Theoretically and practically he was the potential clerical worker of the highest grade, excepting only specialized, technical workers. And we had to pay \$12 a week for this potentiality alone—no experience and only minimum training. The difference then between his \$12 and the market rate on these 32 other jobs represented the money we had to pay on a weekly basis for the necessary qualifications for those positions over and above that required for the office boy. On this basis we distributed to the different elements of the rating scale a given amount of money ranging from 0 to \$38 per week depending upon the position in question. Here was a measuring stick. We checked it and rechecked it until we had arrived at a rating for these 32 jobs which was as nearly argument-proof as we could make it. From then on, every other of the 160 odd jobs is equal to, more than, or less than the measures set up in that original scale for each of the ten elements.

Value of the Rating. Now as to its value, the best I can say for it is, that it has worked. It has seemed to hit the bull's eye in a remarkably large percentage of cases. More important still it has provided a means for us to record with extreme definiteness our impression regarding the elements of the position at the time when the position was being subjected to the closest study and analysis. For future reference that has proved invaluable. Moreover it has provided the means for checking the correct classification of the positions according to the grade description. It has immediately indicated discrepancies, suggesting the need for further check. We have not used the job rating in our discussions with our department heads, but it has provided

the foundation upon which we stood when we were setting forth the reasons for our opinions.

The Establishment of Salary Standards. We are now at the third step in the whole undertaking. The objective at this point is to arrive at fair and practical minimum and maximum salary limits for each grade. The method in general use is to chart existing salaries according to the grade classification. By ruling out those salaries which are abnormally low and abnormally high, we arrive at the general average variation for the grade. At this point it is well to investigate those at both ends of the scale for any given grade. Frequently these high and low spots can be accounted for by age, length of service, or transfer due to a change in organization. When one of these is the explanation, those particular salaries should be entirely disregarded, in arriving at salary ranges. If, on the other hand, such an explanation does not seem to account for the variation, it may suggest the advisability of rechecking the position for some element incorrectly, either over- or underestimated.

Where job rating has been used as an aid to classification, the numerical evaluation is a second indication of proper salary range. The primary function of the job rating, however, is to provide a logical basis for determining the correct relationship of one job to the other. A mathematical formula is usually necessary to convert these numerical evaluations into a salary index. And we would always assume that the best judgment of a group of executives, provided with the wage data covering the company's experience, and wages paid in the community, as well as theoretical indices, would be better than conclusions based upon any one of these factors alone.

Comparison with various companies shows that overlapping salaries for contiguous grades is the usual practice. This may mean that an employee promoted from a lower to the next higher grade will be receiving a salary above the minimum of the salary limit of the higher grade, but for this employee, promotion from the money standpoint means that his upper limit has been pushed that much farther ahead.

There remains to be considered now only the final step.

Salary Adjustments. When we come to salary adjustments, we are in a field where individual company policy will dictate the details of administration. Here comparison of practices between companies will be of minor value since tradition and precedent will pretty surely outweigh all other consideration. However, there are very definite points which must be settled regarding proposed practices. Very briefly, I am listing here the questions which we have under consideration. For some of them the answers are clear in our minds; for others, they are still in the balance.

1. Salaries at present out of line.

We shall not reduce any salaries because of the adoption of a salary plan, although we do hope that promotions may eliminate some, but not all, of present discrepancies. Adjustments upwards will be made gradually.

2. Shall the salary committee pass on all increases or only maintain a checking responsibility for increases granted?

The question is still unanswered for our own organization.

3. What machinery is necessary for maintaining the plan?

We know that a regular follow-up will be essential, as well as a procedure for studying new positions and for reclassifying positions where duties have been revised. Every indication is that this will become one of the functions of the employment department. If we do this we shall be following the example set by other companies.

4. Shall we make salary ranges public?

Not until time has given us an opportunity to bring present salaries in closer harmony with salary ranges.

5. Rating of individual employees.

We are convinced that this will become a necessary part of the plan. We are still studying personnel rating scales and as yet we are not at all convinced that we have arrived at the most essential qualities to be rated.

6. Salary increases.

We believe we shall adopt a regular schedule for consideration of increases, and we think this schedule will differ for the various grades.

Value of the Plan. In conclusion, I should like to quote from the preliminary survey which led our company to embark on the undertaking. One paragraph reads as follows:

Our opinion is that some plan of salary standardization and administration should be adopted which will provide for the studying and grouping of all jobs, which will set minimum and maximum rates for these groups, and which will establish a plan for the reconsideration of salaries at stated intervals. Such a procedure would of itself form the basis of a logical plan of promotion in which there was a direct relation between increase in pay and increase in duties and responsibilities. It would provide the incentive to bring forth the best efforts of our present employees and have the tendency to attract to our force the most desirable of our applicants, and by so doing, it should gradually build up our organization upon the basis of a more contented and efficient force.

Today the objectives remain the same and the probable benefits to be gained from the full incorporation of the plan appear to us to be understated. To them we would add a further advantage. Our present evaluations of our positions are now based, not upon arbitrary rule-of-thumb decisions, but rather upon analytical study resulting in a composite agreement—a foundation out of which is born the confidence of management and employees alike; and confidence is one of the keystones of right human relations.

THE PSYCHOLOGICAL ASPECT OF JOB ANALYSIS

BY RICHARD S. UHRBROCK, *Head Statistical and Research Department,
Industrial Relations Division, The Procter and Gamble Company*

Job analysis is recognized as a valuable tool by executives who control large organizations and who cannot know intimately all the men in their employ. When shops were small, turnover low, and the personal contact between manager and men was possible, there was no need for job analysis. Today, the job analyst stands in the same position as the expert accountant. The job analyst makes a survey of the man factor, just as the accountant surveys and reports upon the material condition of the concern.

As a vital factor in modern industrial management, job analysis is only about twenty years old. In 1911 Frederick W. Taylor stated, "Each job should be carefully subdivided into its elementary operations, and each of these units should receive the most thorough time study."¹ Taylor's mechanical studies had impressed him with the value of having each operation in an industrial establishment performed in the most effective way, by the most effective means. It was but natural for him to apply, to some degree, the same technique to the study of the man factor that he had found so successful in solving the machine problems that he met. He looked for some objective measure of a man's work. He found an objective basis for his study in the amount of work done in a unit of time, or the amount of time required to perform a unit of work. The industrial world was impressed with the possibilities of job analysis when the case of Schmidt was reported.² It will be remembered that before Taylor analyzed the job of loading pig iron, the laborers moved, on the average, about twelve and one-half long tons per man per day. After a system of work and rest periods were worked out for this operation, it was possible to move forty-seven long tons per man per day without injury to the workers.

In this pioneer study the important difference between man and machinery was brought out. Taylor realized that he had to intersperse work with rest periods, for two reasons. First, he had to take care of the actual physical fatigue, due to increased muscular effort. Secondly, he had to avoid the psychological effects of fatigue. The problem was twofold. Schmidt was not to be unduly tired physically, and he was not to get the idea that he was being tired out. Actual physical fatigue and the thought that one is tired are two separate and distinct things.

The evolution of job analysis has been characterized by a growing recognition of the psychological factors involved. At first a few of the time study men were prone to view man somewhat as a machine that was capable of greater production, provided he was properly "adjusted" to his work. We find references to "fitting the square peg into the square hole." Men were selected largely on the basis of the physical requirements of the jobs. Attention was given to "working conditions." Sanitary standards were introduced. Work benches and chairs were adjusted so that they were the proper height from the floor. The lighting system was overhauled, and the proper combination of temperature, ventilation, and humidity was taken into account.³ All these things were done under the heading of job analysis, apparently with the idea in mind that if all the work conditions were satisfactory, the worker would be highly efficient. It took a long time for those in authority to realize that the worker who is physically fit, working in a physically ideal

environment, may not respond as a well-oiled bit of machinery, proving satisfactory by turning out a greater quantity of work.

Wage and bonus plans appeared as a means of helping in adjusting the man to his job. These incentives were supposed to function much as oil helps in the smooth running of a machine. Even these plans did not solve all the difficulties. Changes in salary schedules complicate the situation. Such complications, as a result, tend to emphasize the fact that the crux of the job analysis problem is psychological.

What Is Job Analysis? "Job analysis is a method of scientifically dissecting a job in order to determine the component elements and their influence upon the length of learning period of the worker, production, and labor turnover."¹ It has also been suggested that we view job analysis "as the search for habits necessarily used by a workman on the job." This always has been the ideal of the job analysts, and they have gradually moved from a consideration of the physical to the psychological elements in the situation. As a technique, job analysis has gone through four stages. At first, the employment manager, or one of his clerks, wrote out descriptions of the jobs that had to be filled. These descriptions were often in the form of random notes, briefly stating the major duties involved. As the possibilities of the technique were realized, the random notes were followed by carefully worded narratives, or essay job descriptions. These forms, often elaborate, presented a general description of the work, but proved difficult to handle when analysis was required for the purpose of wage adjustment, or the preparation of a training program. In time, the narrative form was supplemented by a "check list." The common operations performed in the plant were listed, and the job analyst, engaged in investigating a particular job, merely checked the items he found, and added those peculiar to the work under consideration. Finally the job specifications in general use today were evolved. These usually combine the short general description of the job with the check list showing the common elements.

Qualifications of the Job Analyst. As the interest in job analysis grew, it became evident that certain qualifications were necessary for success in the work. In the first place, the man who is selected for the work should be mature and make a good impression on the group whose work he is to analyze. He need not necessarily be what is known as a "good mixer" but he should at least command confidence and respect. His job is to get "job facts" from the men, as well as to observe their work. The job analyst must be able to "sell the idea" of making a complete record of the elements that go into the job. By "job" is meant man and equipment functioning smoothly in the performance of work. Qualities that he must possess are patience and tact. He will find it helpful if he speaks the language of the shop. In analyzing the work of printers one soon finds out that those who set type are not "composers" but "compositors." Among the pattern makers the man who does not have a union card is a "skate." To refer to him in any other terms is to put oneself beyond the pale. The telegrapher refers to the day letter as a

¹ STRONG, EDWARD K., JR., and RICHARD S. UHRBROCK, "Job Analysis and the Curriculum," p. 22, Williams & Wilkins Co., Baltimore, 1923.

"blue" and the night message as a "nite." To know such terms helps in establishing points of contact in talking with the workers.

The successful job analysts keep the men informed as to the purpose of their work. They talk freely about the use of the material in working out training programs, or how the items that make up the job can be evaluated by a salary adjustment committee. In fact, this is one of the successful ways of getting the men to talk. Each one likes to feel that his particular work is the keystone that holds up the arch. If the job analyst can convince the man that the facts he gathers will be put to some practical use he will make his work easier and more effective. The men are averse to the presence of non-producers—"dead heads," as they call them. They feel that each man in the concern should carry his own weight. In most cases this attitude is not expressed openly. The cooperation of the men will be in proportion to their understanding of the work and purpose of the job analyst.

The man on the job may have the required physical qualifications for the work for which he is engaged. Yet, he is a relatively unknown quantity. In the first place, his "mental set," his reaction to the job, is different from his reaction to the employment office situation. The job represents a long-time test. Any measures of his abilities in the employment office are necessarily of short duration. We are all familiar with the men who show up brilliantly in the interview, and who fail miserably at work. The man is a bundle of mental and physical traits, just as his machine is an aggregation of parts. But, with this difference: the machine is relatively static; the man changes from hour to hour, and from day to day.

The Psychological Aspect of Job Analysis. The time has come for a frank recognition of the psychological aspect of job analysis. It has been demonstrated that the objective factors of the job—the tools, material, equipment, light, heat, ventilation, etc.—can be itemized and organized in an efficient manner. This requires care, but the technique is not difficult to learn or operate. One may do all this and still not touch the crux of the problem—the man on the job. As an individual he may have been selected carefully for his work. In a modern industrial plant he may represent the one successful applicant out of twenty.

Job analysts who attempt to take the psychological factors of their work into consideration must adopt the clinical viewpoint. The clinical viewpoint in job analysis begins where the old technique leaves off. It studies the worker as he functions on the job. Gilbreth was aware of the possibilities of this technique.¹ Some splendid work has been done in this direction by a few sales executives who have sent out trained assistants with their men in order to discover and analyze the traits and practices that make for successful selling. As promising as this work is, it has not presented us with a thorough technique for the analysis of an individual worker. It is still possible to itemize the traits a man possesses without giving even a glimpse of his real

¹ GILBRETH, F. B., and L. M. GILBRETH, "Fatigue Study: The Elimination of Humanity's Greatest Unnecessary Waste; A First Step in Motion Study," 2d ed. The Macmillan Company, New York, 1919.

personality.¹ It is necessary to know what "drives" him, what motivates him, in order to begin to explain the pattern of his activities. Two men, working with approximately equal efficiency, may be motivated differently. One may need to support a family, while the other is interested in accumulating enough to purchase a railroad ticket to a distant point.

Job-analysis data should yield material that will enable management to create more favorable working relationships between the tools and materials which it supplies and the strength and skills which the man brings to his work. It is essential to know *what* a man does on a job; it is of equal importance to know *why* he behaves as he does. A job-analysis study is only half completed if it is stopped when a check list of duties is prepared, and a description of working conditions is written. We need to supplement such data by studies of the man himself.

A worker engaged in making machine parts requiring great precision, or a clerk keeping office records, may be provided with practically ideal working conditions. He may have excellent supervision. Yet the work may not be progressing smoothly because the worker is handicapped by defective vision, poor motor coordination, worry, lack of interest in the job in hand, mental deterioration resulting from the effects of an insidious disease, or a host of other factors. Only the study of the man himself will unearth such causes. And only such a study will make job-analysis data meaningful.

The physical and mental inventory of the man should follow the listing of duties and difficulties. A thorough physical examination should be supplemented by a careful psychological inventory, designed to show the worker's intellectual level, his degree of trade skill, his range of interest, and his emotional maturity. Data of that type will be of immediate value in revealing the difficulties that are inherent in the man, rather than in his tools and working conditions. Of more far-reaching significance will be the use of such information in future selection of new workers. Then scientific data, rather than unchecked opinion, will be available to answer the question, What are the physical and mental characteristics of our best men for a given job? The job of the employment office is to pick future workers who are most like the best of the known group.

In the final analysis, it is not management, but the man on the job, who determines how well a piece of work is to be done. The study of his duties will throw some light on his problems and difficulties. The study of the man will aid in determining whether he is capable of doing things differently. If he is untrained, he can be taught; if he is physically or mentally defective, he can be replaced by some one who has the necessary equipment for the work that has to be done.

The Value of Determining Significant Character Traits. The job analyst might well concern himself with the temperamental make-up of the men who require frequent medical care, due either to minor injuries received on the job, or other physical disability. Today we have practically no data

¹ ALLPORT, GORDON W., "The Study of the Undivided Personality," *The Journal of Abnormal Psychology and Social Psychology*, vol. 19, pp. 132-141, July-September, 1924.

that would help in isolating those individuals who tend to break down when high pressure methods are applied. Also, in times of industrial disturbance, the emotional factors involved are of tremendous importance. Take, for example, the normally satisfactory worker who is approached by the labor leader who is aggressive and who has perfect confidence in his ability to sway the opinions of men. Suppose this leader has plenty of "drive" and that he is able to handle complex situations quickly and successfully. If the worker is suggestible, with little drive, and of a class that may be characterized as "emotionally immature," he is as putty in the hands of the leader. If such men are at all common in the plant the possibilities of industrial disturbance are multiplied.

The psychological approach to the problem of job analysis offers unlimited possibilities to the men who are interested in, and trained for, the work. However, the employer who inserts an advertisement for a job analyst with the clinical viewpoint will be disappointed. The men are now being trained in some of our universities. Their real training must, of necessity, take place on the job. The best that the employer can do is to select men interested in the study of the personality of the workers, and then train them in his own plant, holding before them continually the ideal of eventually understanding the drives and traits that serve as the "mainsprings of men."

CHAPTER V

COMPENSATION AND INCENTIVES

WAGES AS INCENTIVES

BY ELLIOTT DUNLAP SMITH, *Professor of Industrial Engineering, Yale University*

The primary distinction between forms of wages lies between paying for the amount of time worked and paying for the amount of work done. This is equally a distinction between remote and immediate¹ incentives. To pay for the amount of work done is to provide an immediate incentive to do as much work as possible. To pay by the month, week, day, or hour provides no immediate financial incentive whatsoever. Under time payments how much the workman does today does not determine how much he will be paid for today's work. Still, time payment is a true financial incentive in the long run. For, how hard the employee works today, and this week, and this year affect what job he will hold in the future and how much he will be paid for that job, and indeed, whether he will hold any job at all.

Time Payments. The simplest form of time rate is the flat rate where all employees doing the same job are paid the same amount regardless of individual merit. The use of flat rates is extensive. One reason for this is the increase of interlocking crews where each worker must keep pace with the others in a carefully timed sequence of operations. In such crews the worker must produce neither more nor less than the standard amount. There is no chance to lag and none to spurt. Often the only incentive to effort desired is an incentive to keep in line—and this is provided by the flat rate backed by the power of discharge.

Another reason for the wide use of flat time rates is because of their value for collective bargaining. So long as any variation in payment is permitted, there is no way of insuring in a wage agreement where between the maximum and minimum the average level of payment will fall. Moreover, once a minimum rate is set by a bargain, even though it may not have been contracted for as a flat rate, since no variation downward is permissible, generally few variations upward are made. Whatever the reason for its use, a flat rate is an incentive to mediocrity—an incentive to attain mediocrity, but because of the deep-seated human yearning for a "fair deal," also an incentive not to exceed it.

Graduated Time Rates. Because of the leveling effect of the flat time rate, graduated time rates are extensively used wherever individual effort and

¹ The use of the word "immediate" by Professor Smith has no reference to Gantt's theory of immediacy—Ed.

attainment is desirable and where bargaining conditions do not interfere. Often graduation in remuneration has been accomplished by combining flat rates for each job with lines of promotion from job to job. Under such a system, while the bargaining advantages of flat rates are retained, there is a substantial financial inducement to do better than the average on the present job in order to be promoted to the higher pay and prestige of the next. A more effective form of financial incentive is brought about when the pay rates within the individual job are also graduated and the amount the workman receives depends upon the production, quality, low waste, or other merits that he displays.

The effectiveness of any form of graduated time payments as an incentive to effort depends more than on any other thing, upon the reliability with which the place of the employee in the wage or job scale is determined. If the employee feels that what pay he gets depends largely on how well he "stands in with the boss," the incentive will be one to propitiate the foreman rather than toward doing better work. If the worker has confidence that the value of his work will be fairly reflected in the amount of his earnings, a graduated time rate becomes an effective inducement to productive effort.

Improving Time Payments as Incentives. Probably the most important steps in improving time payments as financial incentives have therefore been the clearer definition of the reasons for advancement or pay increase, the regularization of pay changes by employment department supervision, and the determination of employee value by accurate records. Records of production have long been widely employed, but recently the technique of rating has developed sufficiently so that ratings of other merits such as quality, versatility, or waste have become reliable. Reliable records and ratings not merely aid management in justly regulating pay, but also make clear to the employee the direct effect of his attainment both upon his remuneration and his standing as a workman, appealing alike to his desires for financial return and for recognition as a worker.

The importance of records and of making the employee aware of his standing and progress removes much of the significance of the distinction often made between "financial" and "non-financial" incentives. Rarely does either stand entirely alone. Always men are paid for their work. Even where flat rates are paid, the hope of promotion to some better job or the fear of losing his job if he falls behind gives to the worker a financial interest in the improvement of his standing, and makes any records a financial as well as a non-financial incentive. Even under the most intensive form of financial incentive, the desire to excel and to gain recognition as an outstanding workman is present and is not destroyed by the fact that the recorded attainment of the worker is also given financial recognition. Piece workers are as proud of their records as high producers as are time workers.

Even with flat time rates, the appeal of the desire to excel and to gain recognition as an outstanding workman is such that skillfully used records may bring striking results. Still, the fact that where flat time rates prevail, one worker gets the same pay as another, regardless of recognized differences in output, causes a patent injustice that goes far to neutralize this appeal. When a properly determined and applied sliding scale of payment is united

with accurate records, however, the non-financial and financial inducements blend, strengthening, not impairing, each other. The value of records of attainment and of financial recognition of degrees of ability are thus largely interdependent.

Payment for Work Done. When the amount which the employee receives each pay day depends directly upon the amount of work he has done, an immediate financial incentive is provided. Before the advent of scientific management, direct payment for results almost universally took the form of straight piece rates. The old piece rates were set either by the hunch of the shop foreman or by a bargain between the union and the company. They were consequently crude and not fairly adjusted to the amount of skill and effort required to make the particular product.

Rate Cutting. The greatest defect in the old piece rate, however, was that the practice of rate cutting was commonly associated with it. Frequently when the employees worked hard for extra earnings and materially increased their pay, the management cut the rate and reduced their future earnings to "a fair day's pay" in spite of the extra effort. Thus, while the piece rate was an immediate incentive to increase output, the fear of rate cutting created a powerful long-run counterincentive to keep production down. Moreover, if any employee, heedless of his individual future, expended exceptional effort in order to increase his present earnings to the maximum, he soon felt the crushing force of social disapprobation against his "killing the rate."

Even where the rates were set by collective bargaining, the employees learned that too high piece rate earnings were not desirable. To a large degree the rates which they were able to secure from their employers depended upon what the average weekly yield of those rates had been in the past. If the weekly earnings under existing piece rates had been above the going wage in the community, the union would have a hard task in bargaining for an increase in or even a retention of the rate. Thus, for one reason or the other, piece rate workers kept their production down. The old piece rate had wasted its substance through riotous cutting.

Effect of Scientific Management. With the coming of scientific management, the same factors that contributed so richly to the improvement of manual technique were applied to the improvement of wage technique and to the restoring of the vitality of direct financial incentives. Conditions and methods were carefully studied and standardized, not merely to make them as efficient as possible, but also to make them as stable as possible. The amount of output which an employee could give when using standard methods under standard conditions was then determined as accurately as possible by time study. A rate thus "scientifically determined" was expected to stand the test of time and was promulgated with the guarantee that it would not be cut unless the method of manufacture was substantially changed. This rendering of the piece rate at once more accurate and secure against cutting, cured many of its former evils.

This development ushered in a host of lesser improvements and modifications. Variety began to appear in the manner in which the financial pressure was applied. The straight piece rate had given a fixed return per piece and

varied neither to mitigate the hardship of the learner nor to stimulate the attainment of a set standard. The newer rates varied in a number of ways for a number of purposes. Taylor advised a differential piece rate that aimed to discourage all but the outstanding workers and to make the reward of outstanding ability strikingly worthwhile. He gave the worker a lower rate of return per piece until a severe "task" had been accomplished in the given time, and after that point he not only increased the rate on all subsequent units produced within the standard time but applied the higher rate retroactively over all that had been produced. If the employee fell short of the allotted task by no matter how narrow a margin, no bonus was forthcoming; if he accomplished it, all that he had done before acquired a new value that made the total increase great. Such a rate not only put a high premium upon exceptional ability and energy in the worker but upon exceptional accuracy in setting the rate. If the task was set too high, the rate would discourage all comers; if it was set too low, the amounts carried home by the worker would soar. It was a courageous investment in scientific accuracy worthy of Taylor, but because of its harshness both upon the worker and management, it was hardly a lead that many would follow.

At the other extreme was the tapering off of the piece payment with each additional unit of output, thus both reducing the risks of rate setting and the strength of the incentive. While such rates, because of their mildness, could be used where standardization and accurate time determination had not been fully accomplished, they had many disadvantages and few advantages as compared to skillfully applied graduated time payments.

Time and Piece Rates. A more fruitful mitigation of the severity of the financial pressure of the straight piece rate is the combination in one form or another of time and piece payment. Because this reduces the amount of the employee's earnings that vary directly in proportion to his output, it reduces on the one hand the management's risk of loss from a mistake in setting the rate, and on the other hand the employee's risk of hardship. While this is, of course, done at the expense of the potency of the immediate financial incentive, the presence of the time rate enables other values than production to be financially recognized. To the same extent that the variation of pay in proportion to output is diminished, the way is opened for rewarding quality, versatility, or other merits. The advantage of this is often great for just as the flat time rate favors mediocrity of output, the piece rate which rewards production only, favors mediocrity of quality.

While efforts have been made to extend exact payment by results to cover quality and waste by providing direct remuneration of these qualities, the difficulty and expense of securing sufficiently accurate measurement of individual attainment per unit of output in regard to these less tangible values have usually proved prohibitive of such measures. In the combined time and piece payment, the long run recognition of quality and similar less tangible values is effectively combined with the direct incentive to output which piece payment provides. This form of payment may vary from one where the direct incentive consists merely of the addition of a small bonus for the attainment of a standard output, to carefully worked-out rates where the proportion of time and piece payment has been accurately determined

so as to produce the emphasis desired and where the particular qualities of employee performance recognized by the time rate are carefully defined and measured.

Standard Time Rates. An important advance in the technique of payment for work done is the statement of output in terms of time, instead of in terms of the number of products or operations finished. Each job is given a definite standard time¹ for its performance, and the employee paid so much per standard hour of work done, regardless of the actual time taken. The financial result to the employee is exactly the same as if the work was paid for by the piece, but the whole problem of calculating production is greatly simplified by having all jobs stated in terms of a time unit. Jobs of various sorts can thus be included in a single computation of the standard times involved, the value of which in planning and work room control is self-evident.

Another important characteristic of standard time payment is that dealings and agreements in regard to piece rates can be reduced to the determination of a single factor. For if a rate per standard hour is agreed upon, all the various piece rates that may exist—no matter how numerous or complex—are thereby automatically adjusted to the agreed level. This not merely provides a ready means of rate readjustment but separates the determination of job values from that of the economic value of labor. This separation enables the relative values of present and even future tasks to be based upon scientific determination of the skill and effort involved, while wage levels are effectively controlled by labor agreements. Standard time rates are thus especially adapted for use in collective bargaining.

The simplification brought about by the statement of output in terms of standard time has made possible a combination of graduated time payment with piece payment in such a way that the effectiveness of each form of incentive is almost undiminished by combination with the other. A graduated time rate is used, but the rate is not paid for the number of *chronological* hours actually worked, but for the number of *standard time* hours of work that the employee completes. Under this plan the long run *rate* of payment is determined wholly, not merely partially, by the graduated time rate, while the immediate payment from day to day depends as completely upon the quantity of production turned out as if only piece rates were paid.

Group Rates. The most recent development of piece rates is the group rate. Its essential principle is the teaming of the employees engaged in making a common product into groups and the payment of each individual in the group in direct proportion to the group output. The group piece rate changes the direct financial incentive into a social incentive. Each employee works not for himself but for his group. Upon him, if he lags, falls less individual loss than social disapprobation of a group, all of whom suffer from his decline in output.

The group piece rate is as well adapted to lock-step conformity as the flat time rate, and in addition provides an effective incentive to the members of the group, while keeping step, to quicken their pace. On the other hand, in

¹ This use of the term "standard time" should not be confused with the name of the Westinghouse incentive plan.—Ed.

those groups where individual attainment is desirable, an individual incentive may be provided by combining the group piece rate with graduated individual time rates, or by stating group output in terms of standard time and making the rate paid per standard hour vary in accordance with individual ability. Individual production records may even be kept and used as a basis on which to adjust the time rate that the individual receives. Thus, in one way or another the group rate may be combined with recognition of the individual.

Group payment permits of the elimination of much of the handling inspection, and counting between operations, which is necessary when employees work and are paid individually thus making a substantial saving. The greatest merit of the group rate, however, is neither its economy nor the combining of social with individual financial pressure: it is the transfer of employee interest and attention from individual attainment to cooperative output. Through the incentive of common interest, the employees where group rates have been installed have developed ways of cooperation that have brought about economies and improvements, and led to increases in output as surprising to themselves as unforeseen by the management. On the other hand, when group rates are used where the method of production is individual and the work of one employee is not directly related to that of another, the inducement to cooperative output is of no value, while the putting of the employee's individual earnings into the common pot dilutes the potency of the individual incentive. Group rates are only adapted to integrated production units.

This last step in the development of financial incentives indicates not only how effectively the financial motive may be combined with the other powerful human motives in bringing about effort, but also how the financial motive may be utilized to arouse and direct upon the job such forces as cooperative interest.

Which Is Best? These, roughly, are the major types of financial incentives in use today. The number of possible—nay, almost of actual—minor variations are endless. It is impossible to say which is best. None is universally superior. As far as I know, none is wholly satisfactory anywhere. There is always room for improvement.

It is unsafe to install any ready-made scheme without careful study of its fitness to the local situation, no matter how many endorsements it may have from satisfied users. Because of the nature of the product, of the methods, of the management, of the employees, even of the community, what suits one plant well and proves eminently successful there may fail in another.

Figures of output or costs "before and after taking," moreover, are not accurate evidence of the value of an incentive plan even in the shop where the figures were obtained. Too many other variables exist; too many other things are likely to have changed while the incentive is being installed and operated. Out of the studies incident to installing any form of direct financial incentive, for example, striking improvements in methods, in conditions and control are likely to have resulted which will show savings entirely regardless of whether the incentive itself has produced results. Besides, care must be taken to distinguish the first results obtained under the interest and attention

a new experiment enlists, from those obtained after the plan has become an old story and its inherent defects have had time to make themselves felt.

Even within one factory, varying conditions may make time rates desirable in one place, time and piece rates in another, Taylor differentials in a third, or some form of group payment in a fourth. Financial incentives have such a variety of forms and influences, and are so affected by conditions that the entire local situation must be carefully studied and the incentive plan carefully adapted to it. Are we primarily concerned with output and content with mediocre quality? Or are we more concerned with quality, waste or some other element? Do we want individual attainment or the keeping of a group in step? Is the problem one where the group as a whole can make a common contribution if made aware of a common interest? Do we desire an intense incentive to reach a certain level, or a general incentive to continue to go as high as possible? How effectively have we been able to standardize? How accurately are we able to measure performance? What human motives can we most effectively appeal to? How much expense does the size and nature of the problem justify? What form of incentive is best suited to the product, the methods, the equipment, the employees, and the management?

Out of the study of such questions and experience with cautious, well-planned initial measures, a plan of incentives can be developed in conformity with the contours of the shop. Such development usually takes time, if only for each of its various steps to season before taking the next. Such a plan should always be considered "in process." Certainly in industry where perfection is so unattainable, and change so unforeseeable, a manager courts trouble if he accepts a plan of human motivation ready-made and then, because he has done so, assumes that it is final and requires no further modification.

Some General Principles. While no form of financial incentive can be unqualifiedly endorsed or condemned, certain principles apply to the problem generally.

1. *The effectiveness of any form of financial incentive depends largely upon the reliability and precision of the measurement of employee skill and effort and the faithfulness with which these measurements are followed as a basis of payment, or of promotion and discharge.* Accurate measurement and recording of attainment are so vital to the effectiveness of an incentive that even flat time rates can thereby be given a vigorous incentive value and graduated time rates given a direct incentive power close to that of piece rates. On the other hand, unless direct payment by results is based upon accurate measurement and recognition it becomes an unjust instrument likely to lead to disaster.

2. *The introduction of direct payment by results, therefore, must follow, not precede the establishment of precise managerial control.* If shop conditions are not standardized so that the amount of effort per unit of output is roughly constant, to introduce production payment is to base a variable reward upon conditions beyond the employee's control. This, on the one hand, will lead to constant complaints and exceptions, and on the other hand to discouragement. No step in the introduction of direct payment by results is more important than discovering in advance as nearly as possible the ideal "one

best way," and then seeing that conditions are maintained at that standard. Until this is done, a carefully administered graduated time rate is a far more effective incentive than a premature attempt at direct payment for work done.

This requirement of standardization, while often an impediment to the introduction of piece payment, is equally often a powerful incentive to management. A company may be as much benefited by the improvements in equipment, materials and methods brought about by the studies preliminary to any scientific introduction of piece rates and maintained under constant pressure from the employees to whose work these rates have been applied, as by the effect of the piece rate incentive in bringing about greater employee effort.

3. *A rate must be set with extremely accurate knowledge of what the employees will later be able to perform and based on scientifically perfected methods, to stand the test of time.* Since the one best way is a dynamic, not a static factor, no matter how much care was taken at the start, in time, gradual improvements in method, material and equipment will usually occur. Earnings will then rise out of all proportion to increased employee skill and effort. Although the change may overall have involved substantial expense, if the development was gradual no single striking change of method will exist to point to as a basis of setting a new rate. The management will thus be faced with the dilemma of having either to pay excessive rates or to "cut rates." Because unforeseeable gradual improvements in methods and working conditions are especially likely to result from operating experience with newly standardized processes, even where careful standardization and rate setting has been done it is often wise in regard to processes where rates have never been applied before to allow rate figures to "season" as time payment records before giving them the rigid finality of established piece rates.

This problem of adjusting rates to gradual improvements of process and conditions, is one of the most baffling problems of handling financial incentives. So far as I can discover, no satisfactory answer to it has been found. The problem is serious at best—if rates have been hastily installed without first standardising conditions as far as possible, it is ruinous.

4. *A financial incentive forfeits much of its power if it is too complicated to be readily understood by the employees.* Regardless of the accuracy of reward of merit, it is only as the employees believe that remuneration varies in accordance with skill and effort that wages have an incentive value. In general, it is unwise to count on employee belief being so firmly supported by faith in the management that it will extend far beyond employee understanding.

5. *In introducing financial incentives one should always count the cost.* Often conditions are such that the exact knowledge of daily output necessary for direct payment by results cannot be obtained without disproportionate expense. This has been most conspicuously true of the expense of inspecting after each operation and of figuring quality ratings in those few places where direct quality incentives have been attempted. There are many places where the difficulty or the expense of standardization and of exact measurement of results are so great that time payments in one form or another are far better than any form of piece payment. Even with time payments and

non-financial incentives it is easily possible to carry record making or other measures to the point of unjustifiable expense. The establishment of an incentive plan, no matter how ideal, is never an end in itself.

6. *In considering any financial incentive, its effect on the whole problem of production, not just upon output, must be considered.* To an embarrassing degree an incentive on one element of an employee's value tends to a slighting of others. If we put a variable rate on output only, for example, we cannot expect the worker to maintain an equivalent interest in improving quality. Again as the differences between group and individual rates indicate, if we pay for individual productivity only, we must not be surprised if the individual fails to embrace opportunities for cooperative action. No form of immediate financial incentive adjusts the pressure of financial interest uniformly. In each case one must ponder the various values it is desired to stimulate, choosing those forms of incentive which emphasize those qualities of most importance in the circumstances, and then seek to offset any undue emphasis by other means such as especially careful supervision in regard to those merits not recognized by the incentive plan.

7. *The financial desire is not the only great force in men.* The employee's whole range of fundamental desires must be recognized. His desires for self-respect, for respect of others, for self-expression and for justice for example as well as for pay are all powerful forces within him. His fears of social pressure, of loss of job or prestige, and of injury or unemployment are likewise fundamental factors. How the working out of the financial incentive affects these forces is always a pertinent question, for we do not apply incentives to an isolated pecuniary desire but to the whole man.

8. *When all is said and done, much of the best value of an employee is too intangible for measurement and reward and, therefore, for stimulation by any form of financial incentive, even the time rate.* Men are too complex and too individual ever to be reduced to slot machines whose entire effort can be compelled by the insertion of a coin or by measurement and recognition. Valuable as financial and non-financial incentives are, their limitations must not be overlooked. Primary among these is the fact that they do not reach the invaluable voluntary cooperation and effort which each workman can give but cannot be forced to give. Such effort arises, not from response to inducements, but from love of his work and loyalty to leadership.

Conclusion. The problem of using wages as production incentives can only be successfully dealt with as an integral part of the larger problem of management. The amount of effort which employees put into their work is influenced by other things besides the desire for pay or the fear of discharge. Besides, employee productivity is as much dependent upon facilities, materials, methods, working conditions, and other factors controlled by management as upon employee effort. To use financial incentives successfully, they must not be treated apart from these other forces that influence men's desire to work or that make their working efforts effective.

Incentives are, therefore, an integral element in management not a substitute for it. Indeed, since the more precise and direct the financial incentive employed, the more highly developed must the management be to cope with it, they make management more difficult, as do most advances in managerial

technique. But they also make a higher degree of management possible. If they are suited to conditions, if they are made part of the general structure of control, if they are employed by an understanding management that realizes their nature and its responsibility, and if they are recognized as only one element among the forces that influence employee effort, they can join with the other forces inducing effort and bring out a response that could be secured in no other way.

If they are properly employed, financial incentives are not a means of reducing man to a mercenary mechanism. The character of an incentive and of what it conduces to, depends less upon its form than upon the character and purpose of the organization of which it is an element.

NON-FINANCIAL INCENTIVES

By ROBERT B. WOLF, *Manager, Pulp Division, Weyerhaeuser Timber Company*

As indicated in the previous paper, the element of financial incentives is always present in some degree, even where work is paid for on a straight time basis. Likewise it is true that few jobs are so dull or uninteresting as not to offer some opportunity to accumulate knowledge, and so the element of non-financial incentives is present when the method of "payment by results" is used. It is necessary, therefore, to define what is meant by non-financial incentives as used in this discussion.

An incentive to increased effort which does not have its origin in a desire for higher monetary reward is a non-financial incentive.

If this definition is accepted it is obvious that the field for the operation of non-financial incentives is not necessarily confined to industries where the method of compensation is mainly based upon payment for the amount of time worked.

It has been my experience, as related in previous papers,¹ that where effective non-financial incentives are used better results can be obtained by avoiding the use of direct payment for quantity of work done. It has also been my experience that avoiding the use of financial incentives tends to simplify management problems instead of making them more complicated. In the previous chapter it has been pointed out that the use of economic pressure makes management more difficult and it may well be that payment for time worked, coupled with intelligent stimulation of those other qualities which grow out of voluntary cooperative effort, will greatly simplify the problems of management. Where financial incentives are the principal means used to spur men to greater effort the necessity for continuously creating more potent devices for stimulating the acquisitive instincts of the workers is always present and troublesome. But perhaps the most prolific sources from which difficulties arise to baffle executives are the problems growing out of

¹ "Non-financial Incentives," American Society of Mechanical Engineers, New York, 1918; "The Creative Workman," Technical Association of the Pulp and Paper Industry, New York, 1927.

the need constantly to readjust unit rates which have gotten so out of line with payment for other work that reductions in rates have to be made. Such reductions almost invariably cause discontent and produce antagonistic human emotions.

As one of the most important functions of the executives is preventing the introduction of frictions which come from conflicting human emotions, it is easy to understand why the use of financial incentives makes management more difficult.

When we work intelligently with the chemical and physical laws of materials in our industrial processes we obtain results with less difficulty. If our difficulties increase we know we are out of harmony with *natural* law. It must be equally true that if we work in harmony with the laws of *human* nature we will make management less difficult, and less difficult it must become if the science of management is ever to provide the foundation for an art of management the practice of which will be pleasure instead of drudgery.

The definition given of non-financial incentives makes it necessary to confine this discussion to the use of incentives which appeal to the creative rather than to the acquisitive instincts of men and this necessitates starting with some conception of the nature of man's creative power and how it normally seeks expression.

The word "man" comes from a Sanscrit root which, in common with such words as month and moon, implies the idea of measurement; and the evidence seems to indicate that man was created for the express purpose of enabling the creative process to take place upon a higher plane than was possible by the generic process alone. In other words, in man the universal creative process is focused in a *single* organism instead of in a genera or type, as in the animal; and therefore individual men, who *are* these focal centers, are conscious of themselves as separate from the rest of creation, and each seeks to comprehend the meaning of the life which surrounds him. This he does by first observing, then recording his observations,¹ and finally by studying the records in order to comprehend the natural law operating within the phenomena he is observing. To illustrate: the savage who wished to cross a body of water too wide for him to swim built a raft, because wood, which is lighter than water, floats upon the surface. In the course of time he discovered that the solid wood forming the heart of the log could be replaced by something useful. Later ships were built of many logs, until finally the law was formulated that anything will float which, bulk for bulk, is lighter than the liquid displaced. Today the ships of the world are built of iron (a thing the old shipbuilders declared impossible) by creating special conditions for the floating of a metal that would naturally sink, because iron, bulk for bulk, is heavier than the water it displaces.

It is difficult, but not impossible, to imagine any other sequence of creative evolution than that which has taken place upon the earth. The mineral,

¹ This recording, in the beginning, was a simple memory process, later a word of mouth tradition, and still later evolved into the written word and symbolism of the graphic arts, through which the significance of events within a particular natural phenomenon could be apprehended.

vegetable, and animal evolutions, each with its own functions, and therefore with its own laws, preceded the human; and it was by virtue of logical necessity that man's major function should have been what it is, namely *the creation of new forms from preexisting substances by consciously working in harmony with the laws inherent in the natures of these substances.*

From the foregoing it is apparent that the amount, quality and value of man's creative power is directly dependent upon his ability and capacity to accumulate knowledge, and the skill he develops in using this knowledge wisely, *i.e.*, in harmony with universal law.

In industry, therefore, the problem is to develop a science and art of measuring individual and group accomplishment so that those responsible for the various functional operations can quickly visualize the past in order more intelligently to retard undesirable, and accentuate desirable trends.

Use of Records Measuring Accomplishment. The following is a description of the way records measuring accomplishment were introduced into a paper mill:

The publishers are particular about the weight of the paper. A ream, to be satisfactory, should weigh exactly thirty-two pounds. Paper that is lighter is apt to cause breaks in the pressroom. If it runs heavier, the paper cost per edition will increase. Furthermore, if the paper is very dry it becomes brittle and is apt to break. The dryness, too, prevents the paper from taking a good finish. As a result, the surface will "fuzz" up and fine particles will come off on the printing press and cause trouble by filling up the type and depressions in the cuts.

In the ordinary course of events the publisher sent his complaint in to the sales office, where it was passed on to the manager's office. The matter was then taken up with the superintendent and he passed the "kick" along to the boss machine tender. It finally reached the machine tender, or back tender, or any member of the machine crew who was responsible. This process had to be repeated constantly in order to maintain a uniform quality of paper.

Obviously, therefore, the trouble was due to lack of interest upon the part of the men in charge of the machines in keeping operating conditions as they should be. This lack of interest came largely from a lack of knowledge as to what the conditions actually were. We determined, therefore, that more samples should be taken to give the machine crews accumulative information.

The usual method was for the back tender to take a sample of paper every time a reel was changed, weigh it, and let the machine tender know the result. The machine tender then turned on or shut off stock, according to whether the sample was light or heavy.

A sample from the front, middle, and back of the sheet was taken occasionally but, as a rule, not so often as it should have been taken, largely because the men had not the time.

From previous experience, we knew that the problem was to produce a desire upon the part of the machine crew to get the desired results, so on each shift we put a man (one for every two paper machines) to take samples every time a reel was changed (from the front, middle, and back of the sheet), these samples being weighed and recorded as shown in the reel record (Fig. 1).

In weight of samples columns are shown the weights of the sheet at the front, middle, and back; the top figures being the weights before drying and the bottom figures the weights after drying. From these figures the uniformity record figures are obtained by calling the middle (numerical) weight normal and taking off ten points for each quarter pound lighter or heavier for the other two weights. In the total weight columns, the reel average figures represent the average of the samples from the front, middle, and back of sheet. Figures in weight record columns are obtained by calling 32 pounds per ream 100 and taking off twenty points for each pound above or below 32 pounds. In per cent moisture columns, the three figures in the first column show the actual per cent moisture in samples; the second column, the average of these samples; and the third column, the accumulative shift average. Figures in moisture record columns are obtained by calling 8 per cent moisture 100 and deducting twenty-five points for each per cent above or below 8 per cent. Pop test shows the strength of the sheet; the first column by samples, second column the average of these samples, and the third column the accumulative shift average.

These forms were kept in the machine room, at the end of the paper machines. While the sample testers were instructed in the work by the research department, they were controlled by the boss machine tenders and were largely recruited from the machine crews.

There was no thought in the minds of the men, therefore, that this was a follow-up system, designed to enable the management to find fault with the workmen. They recognized it as a system to help them to get information which they did not have time to get for themselves, and which they needed in order to do their work intelligently. In other words, we were recording the facts which enabled the operators to recognize the natural laws underlying the process.

The suggestions regarding the moisture test (in addition to the weight) came from the international president of the Paper Makers Union. It proved to be a great help, for previously the only way the back tender could tell anything about the moisture content of the sheet was to "feel" it as it passed from the calender stack to the reel.

Of course, no record could be made of this feel to enable the back tender to tell how well his work was being done, so there was no particular reason why he should have been interested in this part of his work. It is only the exceptional man who has imagination enough to create within himself a consciousness of his progress.

The progressive improvements, shown in the charts in Figs. 2, 3, and 4, indicate clearly the increasing interest in the work and how completely the man became master of the machine. That this improvement was due to increasing interest alone is borne out by the fact that we did not pay a man more money for a good record, but paid the prevailing union scale for all positions. These were adjusted each Spring by joint conferences with the men. In this way we kept a proper wage balance between the different classes of work in proportion to the skill required, and as a consequence avoided all the innumerable difficulties which confront the piece-work system, task and bonus plans, and other direct-payment methods.

FIG. 3.

FIG. 4.

It is often argued that it is not right to pay a good man the same rate as a poor man and with this I agree; but the fact is that when these progress records are furnished to men, all men in a certain operating class finally come to be practically equal in performance and the difference will be only between the amount of skill required in each different class of work. And in these *classes* there is a difference in compensation.

Invariably the competition was keen enough on all quality records to bring nearly all the men (who had been at the work a sufficient length of time to become expert) practically to the same degree of proficiency.

The period was four weeks and the average to date began all over again at the end of each four weeks' period. The reason for indicating the standing of the men on a period average, rather than the day's average, is that it tends toward greater continuity of effort, which in itself is a source of much greater satisfaction to the workman. It is the steady progress that really counts and not the spasmodic, spectacular high record for any one day. The record, to give joy to the worker, must reflect the constant steady inner urge which indicates the degree of his mastery of the forces he controls in the day's work.

The "uniformity" record, shown first in the three charts in Fig. 4, came as the result of suggestions from the men, after the weight and moisture records had been in use for some time. We find that the greater number of factors or laws that we record, the greater is the interest in the work, because they bring to bear upon the problem a greater amount of thought.

The "basis weight" and "moisture test" records had been operating only a short time when the machine tenders called our attention to the fact that they could get better results if the stock consistency furnished them by the beater room were more uniform. They asked us to find a way to measure the consistency of the stock, so that the beater engineer could do his work better.

As a result of this suggestion and after discussing the matter with the beater engineers, the research department tackled the problem of measuring this stock thickness. The beater engineer pointed out the fact that the consistence of the stock which was furnished to his department by the sulphite pulp mill and ground wood mill, was not uniform and that we should find some way of recording the consistency at these points.

We found that to do this we had to increase the amount of agitation in the pulp storage tanks and, as a result, made some radical improvements, which produced greater uniformity throughout the entire process.

Right here it might be well to call attention to the fact that our experience has been that men do not have to be stimulated to make suggestions by offering prizes. They are glad to suggest improvements, for in this way they are helping to create conditions in the plant which help them to get better results (the results being indicated by their progress records). Then, too, they were certain to receive recognition for their suggestions, for the foreman knew he would be judged by how well he succeeded in getting his men to use their brains. He naturally hastened to give credit for all suggestions made.

Of course, it goes without saying that this greater uniformity is bound to result not only in a better quality of paper, but in increased output as well; in fact, in one mill, an increased output of over 5 per cent was quickly obtained.

We further made the discovery that what is called the "slowness" or "freeness" of the stock had quite a bearing on the quality of the paper as it came off the paper machines, and as a result we adopted a method which recorded the slowness and freeness. By free stock I mean stock that the water leaves rapidly, and by slow stock a stock which the water leaves slowly. We found, incidentally, that this slowness and freeness is one of the best indexes of the quality of the groundwood pulp, and we developed a series of factors which recorded the operations of the grinders upon which the wood blocks are reduced to pulp.

This work had always been one of the most uninteresting and monotonous jobs in the plant, but it was converted into an interesting operation.

Kinds of Progress Records. Progress records can be grouped into three general classes: *quantity* records, *quality* records, and *economy* records.

Quality records are, perhaps, of the greatest importance, for they bring the individual's intelligence (brain power) to bear upon the problem; and, as a consequence, by removing the obstacles to uniformity of quality, remove at the same time the obstructions to increased output. The creative power of the human mind is, however, not content simply to produce the best quality under existing conditions of plant operations. So the desire to create new conditions for the more highly specialized working out of the natural laws of the process demands expression, and this expression at once takes the form of suggestions for improvements in mechanical devices.

This desire contains within it the germ of economic thought, which will unfold and express itself eventually in a request for cost records, and the organization that neglects its opportunity to satisfy this desire is overlooking one of the great avenues leading toward intelligent productive effort.

Because of the interrelation of quality, quantity, and economy records, any complete record of individual progress must, of course, take them all into account. However, this is not always practical, but at least one of three ways of measuring progress is always open.

Necessity of Using Individual Records. As further illustrating the necessity for giving individual records to the men, we discovered that the back tenders, who sometimes worked on other shifts than their regular ones, lost interest in their records to a certain extent when on a different shift. Therefore a request came to keep the back tenders' records separately, so that, no matter what machine tender he worked for, his record would follow him. This was done and the two records of Nov. 29 and May 9, reproduced in Fig. 5, show clearly not only the gains made but the increasing competition for a good record.

Mistakes in records cause a lack of confidence. We overcame this trouble by giving "accuracy" records to the "sample tester." We had the research department check over the number of mistakes made each day in the "reel record" sheets. A perfect score with no mistakes we called 100 per cent; two and one-half points were taken off for every mistake. An average of eight to ten mistakes a day was a common occurrence but almost immediately this changed so that today a mistake is decidedly the exception.

Use of Cost Records. Cost or efficiency records stimulate the greatest interest in work, so I will give examples of their application.

Below is shown a foreman's detail job sheet, which indicates the method we had for giving our maintenance foremen cost records of their work (see Fig. 6).

It was obviously a difficult matter, when dealing with maintenance and construction work, to give quality or quantity records, as the work varied

so much from day to day, so the only kind of records we could furnish economically were records of cost. The original suggestion to give these records grew out of the fact that we gave to each operating department head a complete cost of operating his department, for which he was held responsible. As soon as he began to realize this responsibility, because all the repair

materials were charged to him, he at once began to make intelligent criticisms of the engineering department, and especially was he critical of the maintenance foreman if he was wasteful in the use of materials. As a result of this, the maintenance foremen asked the master mechanic if they could not have job costs showing how economically they were doing their work, as they had no idea of the value of the materials they were using. The foreman's detail job sheet shown is the result of this request. It will be noted that the

FIG. 6.—Foreman's job sheet.

job is fully described, the total cost of material and labor to date is given, as well as the cost of labor and material for the previous day. Then below is listed the itemized cost of all materials used. The men soon became educated as to the value of the materials they were using and we noticed a great change in the amount of waste; in fact we had frequent cases where maintenance men would bring scales into the mill to make sure that the storehouse was giving them full measure of materials, and we were soon obliged to get up a system of giving credit for material returned to the storehouse in order to help foremen keep down their job costs. This was in no sense a form of contract system, for all of our maintenance and construction men were paid by the hour and did not receive any more money for doing a job economically.

The following graph shows the concrete results obtained by giving the cost sheets to the department heads and job costs to the maintenance foreman (see Fig. 7).

It will be noted that there was a rapid increase in production from 1908 to 1913, also a rise in repair material used, as well as an increase in the cost of maintenance labor. The fourth curve, showing the amount of material

FIG. 7.—Showing concrete results of cost sheets.

used for each dollar spent for maintenance labor, is more or less a resultant of the other two. The gradual rise from 1908 to 1911 in this curve was due to the increased material consuming power of the maintenance men because of the introduction of labor-saving devices, such as pneumatic and electric portable tools. There was a drop in the figures in 1912 and 1913, but we were unable to get a real thought of economy started in the plant until

the departmental cost sheets and job cost sheets were started. These were first put into effect in 1914 and there was an immediate drop in the curve from an average of about \$2.15 worth of material spent for each dollar spent for labor, down to \$1.55 in 1914 and \$1.05 in 1915.

That this drop was due to the greater economy and thought in the use of materials is indicated by the fact that our maintenance crew was not very much reduced, the saving coming almost entirely in the use of materials.

The drop in production in 1914 and 1915 was due to war conditions, which were unavoidable. It is a significant fact, however, that in spite of this drop in production the maintenance material cost per ton of pulp was reduced to approximately one half the amount under the conditions of higher production during the two preceding years.

Increase Not Secured by Use of Bonus. In none of this work did we pay bonuses to a superintendent, department head, or workman; our salaries and wages were high, but payments were all on a monthly, weekly, or hourly basis. The increased effort, therefore, came entirely from a desire within the individual to be productive. Of course this sort of creative effort produced great changes in operating conditions. We increased our yearly production from 42,000 tons to 111,000 tons without adding to the number of digesters for cooking the pulp, or wet machines for handling the finished product, and we changed our quality from the poorest to the very best.

Value of Non-financial Incentives. In conclusion, it should be said that there is nothing essentially difficult about putting non-financial incentives into operation. Conforming, as they do, to normal human instincts, they are not opposed but welcomed by workers.¹ No one can possibly offer objections to being furnished with information; and information furnished regarding progress in increasing production, bettering quality, and lowering cost of output can be furnished, to great advantage, to all individuals responsible, whether be they individual workers, foremen, department heads, or higher executives.

The problem of management is how to increase the number of men who have knowledge of the laws inherent in the materials and processes they are handling, who appreciate the progressive and accumulative effect of their own actions upon the materials and processes for which they are responsible, and who see the relationship of their own work to the finished product and to the organization as a whole.

Managements most successful in solving this problem are making the greatest progress, for in them exists the maximum of coordinated effort.

Finally, relative compensation should be based upon the amount of skill and intelligence required for each type of work. But the inducements and incentives to increased effort are, in the long run, more potent if the separatist acquisitive instincts are not aroused; in other words, if the incentives to increased effort do not have their origin in a desire for increased monetary reward.

¹ I have found this to be true of workmen both inside and outside the trade-union movement.

THE USE OF GROUP INCENTIVES

By C. C. BALDERSTON, *Assistant Professor of Industry, University of Pennsylvania*

Subdivision of labor multiplies the varieties of jobs, but modern methods, such as the use of conveyors, tend to link many of them together again. The resulting interdependence of operations furnishes the chief reason for group incentives. If work is flowing continuously from one worker to another, the speed of the latter depends upon that of the former.

By group incentive is meant financial payment which is based on the combined output of a number of workers. If jobs are closely related, workers in a group can help or hinder each other and the logical basis for a bonus is the performance of all of them. But jobs which are wholly independent of each other call for extra-compensation based on the output of each employee.

By-products of Group Incentives. In addition to the reason cited above, managers who have used group payment have noticed a number of important by-products.¹

It is a spur to cooperative effort rather than individual self-interest.

It is argued that the social pressure within the group encourages slackers to increase output, whereas individual incentives exert pressure upon the rapid workers to "peg" their production.

It offers an inducement for employees to utilize their spare time on another operation performed by the team. When the jobs are arranged progressively along a conveyor, the use of spare moments to help out those who are behind tends to keep the operations in balance even when the rate of production varies.

It stimulates the training of new employees by their fellow workers and the exchange of trade knowledge.

In order to increase the group efficiency, operators assist in planning and supervising their own work.

Where the flow of work is not controlled mechanically, it is speeded up because the output must pass the "payment point" to be counted.

It reduces the clerical costs incident to the payment of incentives by simplifying the counting of the work and the computing of the pay roll.

In the application of group payment, only part of the problems which arise are different from those encountered with individual incentives. Therefore the features which seem to characterize successful plans are for convenience divided into two classes:

Those which are common to both group and individual payment.

Those peculiar to group plans alone.

The following discussion of these problems is necessarily dogmatic because of the limitation of space.

Guiding Principles Common to Group and Individual Incentives. The objectives which it is hoped to attain by the use of incentives will be clearly defined by management, and the plan designed accordingly.

¹ This section, as well as a considerable portion of the remainder, is taken from C. C. Balderston, "Group Incentives," University of Pennsylvania Press, 1930.

The factors which affect output, other than the operator's skill and effort, will be brought under reasonable control by management. (These factors include the steadiness of the flow of work, the size of the lots worked on, the quality and uniformity of the raw material, and the condition of the machines and equipment).

Careful analysis and measurement (time and motion study) to determine uniform tasks or piece rates will precede the use of financial incentives.

Before the selection of any incentive system (or bonus curve) an investigation will be made of its effect at various efficiencies on unit costs and employee earnings.

Reliable records will be available of output of the actual time worked. These records will serve both for the pay-roll computation and as non-financial incentives to stimulate interest in improving performance.

Adequate protection for the workers will be provided to prevent the destruction of morale.

The task time will not be reduced unless the methods and equipment change substantially.

Allowances will be made for unusual events outside the control of the workman which cause the reduction of his earnings.

Problems Peculiar to Group Incentives and Typical Methods of Solution.

The problems which are characteristic of extra-compensation on a group basis may be summarized under the captions below.

1. The composition of the group.
2. The determination of the best unit of work in which to measure output.
3. The research work, or time study, prior to setting the group tasks.
4. The decision as to the level of difficulty at which the tasks are to be set.
5. The relation of extra-compensation to output (i.e., the choice of the earning curve).
6. The distribution of the earnings of the group to its individual members.
7. The protection of the employees against influences affecting their output which are uncontrollable by them.

1. *Composition of the Group.* The key to the most effective formation of groups is the degree to which the individuals can be mutually helpful. This depends partly on the interdependence of the jobs, and partly on the existence of opportunities to aid others by direct assistance during idle moments or by trading information.

The smaller the group the greater is the social pressure and the money stimulus felt by each individual. That the groups be kept small is especially important if a strong incentive is desired. For miscellaneous work, groups of fifteen or twenty men (and not exceeding forty) are favored by many managers. Where the work is highly mechanized, however, the size of the groups may be enlarged both to reduce clerical expense and to throw the attention of the entire force upon the maintenance of the production schedule.

2. *Units of Work.* The questions which must be solved prior to the introduction of incentive payment are of two types: those to be answered by research or investigation; and those to be settled by executive decision.

Perhaps the first of the research problems is to select the unit of work in which the task is to be assigned and actual output measured.

The logical guide to the selection of the unit of output is to determine the real nature of the work done. On an assembly line, the purpose is obviously to put together subassemblies and parts into a final product which will pass inspection, and the unit of work will inevitably be in terms of completed product. But for indirect labor, such as that employed in receiving, shipping, or trucking, the answer is not always so simple. *The unit chosen for counting the output should above all else reflect the effort and time expended.* For example, if the time varies with the weight rather than with the number of pieces handled, then some weight unit like the ton should be used rather than the number of pieces.

In addition to this all-important characteristic, the unit selected for each operation should be definite and capable of objective measurement. Feet, pounds, and number of items are clearly understood, but qualities such as the cleanliness of a department permit many interpretations.

The task may be expressed either in time or money; that is, either in hours per unit of output or in dollars per unit of output. Trivial as this distinction may seem, it is at the center of one of the most debated points in the use of group incentives. When the task is expressed in standard hours, a group incentive plan is usually referred to as "group bonus." But where the task is expressed in dollars, the arrangement is ordinarily called "gang piece work." The chief effect of this distinction is felt in the distribution of the earnings of a team to its constituent members which is discussed in a later paragraph.

3. *Research Work Prior to Setting the Group Tasks.* When the operations are not on a conveyor, the grouping of individual tasks tends to level out variations in the difficulty of their accomplishment. But group payment demands the same careful analysis and precision of measurement which ought to precede the introduction of any incentive. The standardization of operating conditions, the time study and other statistical analysis which are essential to make the tasks of various groups sufficiently uniform are almost identical with the preliminary research needed for individual incentives. There are, however, three important variations.

One unusual problem encountered with group payment is to set a group task for operations which are already performed on a conveyor at the time the incentive is installed. Naturally, the most effective balance of jobs will differ with variations in the design or finish of the product.

A second difficulty is that group incentive makes it both possible and desirable for certain indirect workers to be included in the group if they are in a position to facilitate the work of the direct operators. These indirect operations, however, such as trucking and routine inspection are often of such a nature that they cannot be time studied with the same precision as the repetitive jobs. If they are to be included, however, it is essential that they should be analyzed with extreme care in order that the approximate uniformity of the tasks may not be destroyed.

A third difficulty which is encountered in heterogeneous work (i.e., operations which are similar or related, but which are not identical nor on a conveyor) is to relate all of the task times to a simple unit of output. For example, the work of a group of Elliott-Fisher operators or other clerical workers may

include a percentage of items which are identical and easy to type. In order to use a simple unit of output such as 1,000 items, it is necessary to make a statistical study to discover what percentage of the total items tend to repeat themselves. After the proper task times have been determined both for typing the repeat items, and those which are not repeated, the times can be combined by weighting them according to the distribution found by the statistical study.

The Difficulty at Which the Tasks Are Set. The decision as to the level of difficulty at which the tasks are to be set is not essentially different under group and individual payment. But since the solution must be considered in the light of its psychological effect upon the workers, it must be remembered in the case of group incentives that the efficiency which can be attained by a gang of men is lower than that which can be reached by exceptional individuals. In making the decision as to the level of difficulty, the following factors will need to be considered:

The degree to which close managerial control can be maintained. This, in turn, will depend upon the extent of standardization and will affect the precision with which task times can be set and the amount of protection which is necessary for the workers.

The existing efficiency of the plant and the ability of the management to increase that efficiency before the bonus becomes operative. This will influence the selection of the point at which employees start to earn a bonus.

The judgment of the management as to the psychological effect upon the worker. Some executives believe that workers should "beat" the task rather than fail to reach it. If too high, the tasks may tend to discourage, and if too low, they may not prove a goal to be attained.

The share of the saving in labor cost which will be paid to the workman under the payment system which is adopted.

The Relation of Extra-compensation. In determining the price which the company is willing to pay for additional output (i.e., additional efficiency), the amount of extra pay may be related to output by using any one of a number of so-called "systems." Among those which are employed most often for group incentives are the Wennerlund efficiency scale, used by General Motors; various kinds of standard hour plans, such as that of the Packard Motor Car Company and the Timken Roller Bearing Company; the Bedeaux point principle, used by Swift and Company; and the Rowan premium plan used by the General Electric Company.

The choice of the proper earning curve depends upon the extent of precise control in the plant, the accuracy with which maximum performance can be predicted, and the ability of the management to raise the existing efficiency of the shop before the incentive becomes directly effective. These factors are alike under group and individual incentives except that, under the former, it is especially important that the formula be simple to compute and easy to understand, and that it permit the group earning to be distributed fairly.

Distribution of Earnings of the Group to Its Individual Members. The distinction between so-called group bonus and gang piece work is important because of its influence upon the allocation of the group earnings.

The usual method of allocating gang piece work earnings is to assign separate base rates to each man according to his effort and ability and to apportion the earnings of the gang according to the product of the individual base rate and the actual hours worked on incentive by that individual. After the base rates are multiplied by the hours worked by each man, the sum of these products is divided into the total piece-work earnings of the group. The resulting percentage, if over 100, is then applied to the base-rate earnings of each man.

If the gangs are small in size, this method of apportionment tends to create personnel difficulties because an increase in the base rate of one individual decreases the earnings of all others in the group. Consequently, in groups of twenty or under, the older employees tend to resist the granting of raises to the new members to reward them for improvement.

With a group bonus, however, these personnel difficulties may be avoided. All members of the same group get the same percentage of bonus, but since the percentage is applied to the individual base-rate earnings, which vary with the skill of the operator and his actual working time, the absolute amount of each bonus may be different. The procedure usually followed is to determine the efficiency of the group by dividing the task time by the actual time worked. Then, by locating this percentage of efficiency on the bonus curve, the percentage of bonus to base pay is determined for the period in question. The amount of each individual bonus in dollars is figured by multiplying the individual base rate by the actual hours worked by that employee, and applying to this product the bonus percentage of the group. If an individual's base rate is 50 cents an hour and the actual hours worked by him are fifty, his base-rate earnings are \$25. If the percentage of bonus earned by his group is 20 per cent, the bonus of this individual equals \$5 and his total pay is \$30.

The advantages claimed for this method of distribution are:

That it combines an individual stimulus with the group incentive because the individual base rates can be changed to reflect improvement in effort or ability.

That the base rates can be changed without affecting the task times, and consequently the direct labor costs are sensitive to changes in the labor market.

The Protection of the Employees against Influences Affecting Their Output Which Are Uncontrollable by Them. Since incentives of all kinds depend for their effectiveness upon the psychological reaction in the minds of those who work under them, protection against real or fancied unfairness is vital to the best results. Not only does such protection prevent many grievances, but it is desired for its own sake by managements which believe that an honest attempt to be fair is essential to sound personnel relations.

A precept of management which has been repeated times without number is that, unless the equipment or method is changed substantially, a rate should not be cut, and that if it is cut, the consequences are undesirable. A more specific statement of this rule is that the time allowed to perform an operation will not be reduced unless the operation has changed. Substantial changes in material, equipment, or in the product itself obviously call for the setting of a new task based upon a fresh time study.

In order that the earnings of the group may reflect the combined effort of its members as closely as possible, it is important that these earnings should not be affected too much by variations in material, equipment, working conditions, or the quality demanded. Since the maintenance of the standard conditions for which the task is set is a responsibility of management, most employers protect their workers against failure to maintain them.

The earnings of a group are affected adversely by the introduction of new employees if they are inexperienced and untrained. Executives usually feel that fairness to the old employees demands that they be protected against the reduction in their earnings during the time that new employees are reaching the normal efficiency of the group. The training time varies, of course, with the difficulty of the job and with the experience of those who are hired. Many employers follow the policy of dividing the burden equally between the company and the old employees by carrying new employees on day rates for approximately one-half of the time necessary for the average person to reach normal output. The arrangement in these cases is for the company to pay the new employees on a day-work basis for a given period and to credit their output during this time to the gang.

Basic Principle. It should be emphasized again that incentives ought not to be applied to groups unless the jobs are interrelated. In situations to which they are adapted, they tend to develop teamwork and group spirit rather than individual self-interest. They not only spur the worker to greater accomplishment but insure that his advancement can be secured only as a member of a team, and not as an individual working for his selfish interests alone.

SUGGESTION SYSTEMS

By A. B. GATES, *Director of Training, Eastman Kodak Company*

Suggestion plans have been in use for many years in a variety of types of business organizations. These plans have met with a varying degree of success, and some have been abandoned because of apparent failure. A survey of the causes of success and reasons for failure discloses some of the features that should be embodied, and others that should be omitted, if the plan is to succeed. The purpose common to all suggestion systems seems to have been the provision of a medium through which the employees will be encouraged to submit to the management ideas on possible improvements.

The principal cause of failure in the plans which have not met with success or which have gradually lost the employees' support has been indifference on the part of the employees. This indifference can usually be traced to one or more of the following causes:

- a. Poorly introduced system.
- b. Improperly planned routines.
- c. Lack of interest on the part of management.
- d. Hostility of supervisors.
- e. Delay in considering suggestions.
- f. Insufficient awards.

Purpose of the Suggestion System. Although the system should provide a medium through which the employees may submit ideas on improvements, the idea back of the plan should be a real encouragement to the employees to think about their work and the company's problems. The plan should in reality be an invitation to the employee body to participate in that phase of management which has to do with planning methods and procedures. In this respect, the suggestion plan is similar to an employees' representation plan. That management attitude which will insure the success of a representation plan will also bring success to a suggestion system. Management must be conscientiously and unselfishly interested in the plan if it expects the employees to support it by their effective participation.

Establishment of a Suggestion System. Management should first convince itself that it should establish a suggestion system. By an analysis of the business organization, procedures, and methods, a decision should be reached as to the types of suggestions desired. In general, it has been found that desirable suggestions may be classified into types or groups, among which these are usually included:

Improving engineering, construction, operating, manufacturing, or sales methods.

Improving service to, and relations with, customers.

Improving public relations.

Improving office methods and systems.

Improving tools, appliances, and machinery.

Improving health and working conditions of employees.

Improving safety devices.

Eliminating hazards to life and property.

Eliminating unnecessary work.

Reducing costs.

Preventing waste.

When management has decided that the business operations offer ample opportunity to warrant the establishment of a suggestion system, it should carefully work out all the details of a formal plan. The plan should provide for:

A definite basis of award.

A permanent executive secretary to look after the details and to insure prompt action.

A definite procedure for receiving, acting on, and making awards on meritorious suggestions.

A definite routine for the disposal of unaccepted ideas.

A definite provision as to what classes of employees shall be eligible to awards for suggestions.

A provision to give credit to suggestors if ideas, once rejected, are later put into use.

A provision to insure as nearly uniform valuation of suggestions as possible.

Obtaining the Support of Executive and Supervisory Groups. With the details of the plan completed, the management should first obtain the wholehearted support of the supervisory employees. This can best be done by a thorough dissemination of information about the proposed plan and its purpose to the

executives, subexecutives, and supervisors, prior to its announcement to the employees.

One of the most common causes underlying the lack of support of a suggestion plan on the part of some of the supervisors and executives is the mistaken idea that employees should voluntarily submit any ideas that they may develop as a result of their work, without the necessity of a reward beyond their regular compensation. Another is that the approval of such suggestions is a reflection on the responsible supervisors and executives for not having developed the ideas themselves. Both of these difficulties will undoubtedly be found in almost every organization. In many organizations successfully operating suggestion systems, the first of these problems has been solved by the establishment of the idea throughout the supervisory and executive forces that the employees are, in general, compensated for more or less definitely assigned tasks, and that, through the suggestion system, management is asking the employees to render an extra service to the company, for which the company is willing to pay as it would in the case of extra production of other character. The solution of the second problem is obvious. Two heads are always better than one, and it is a shortsighted policy that induces the employees to withhold from management ideas on possible improvements. Future supervisors and executives will probably be taken from the working force, and any plan that will encourage the employees to think in terms of improved efficiency and methods will greatly enlarge the available material when opportunities for promotion develop, and will make for a more alert supervisory force.

Announcement of the Plan. Following the decision to establish a suggestion system, the management should forward to each department or unit head a complete description of the plan, including instructions regarding its operation. At the same time, by means of a letter to each employee or by bulletin announcements, or by both, the employees must be given complete information as to the purpose and provisions of the plan, including instructions as to methods of submitting suggestions, and of making awards. The announcement to the employees should also include suggestions as to types of ideas on which management desires suggestions.

Organization and Set-up of System. There should be a secretary appointed who will be responsible for the necessary routine to insure prompt action on the disposition of all suggestions submitted. These duties can usually be assigned to a staff employee who can handle this work without interfering with other company routine.

Suggestion Committee. A committee is not necessary to the successful operation of a suggestion system, but in many organizations, the committee plan has met with general approval. As this form of organization is simple in its operation, and as the principles involved can readily be developed, it will be used to discuss the principles, methods, and procedures involved in setting up and operating a suggestion system.

The committee should be under the chairmanship of a major executive. The committee should include in its membership representation of at least each of the major divisions or units or organization such as: engineering, production, research, financial, accounting, and sales. Each member of the

committee should act as sponsor for suggestions having to do with work or methods relating to the unit of the organization which he represents.

Subcommittees. Provision should be made for the appointment of subcommittees to consider suggestions or groups of suggestions when they are received.

Suggestion Blanks or Forms. Suitable blanks or forms should be provided for the use of the employees in making suggestions. These forms should be serially numbered, and each form should carry a detachable stub on which the number of the form should be duplicated. The forms should also carry complete instructions to the employees as to how suggestions should be submitted and how awards will be made.

Suggestion Boxes and Bulletin Boards. At suitable locations throughout the plant and office, bulletin boards should be located for the posting of notices and instructions regarding the operation of the system. Containers for blank forms should also be attached. If company mail is not to be used in submitting suggestions, a box in which the employees can deposit suggestions should be set up as a part of the equipment at each location.

Awards. In most plans, it has been found that cash awards are desirable. In many plans, the minimum award is set at \$5. Some plans provide for a uniform award of \$1 for all accepted suggestions, with provision for additional awards to the individual making the greatest number of accepted suggestions in a given period, and some plans provide for additional awards for the best, second best, and third best suggestions in a given period.

Subsequent Award after Suggestion Is Put into Effect. A quite common provision in the more recently established plans is to make an award on the apparent value of a suggestion and then, after a period of six months or a year, audit the results, and if the suggestion is found to be of greater value than was anticipated, make an additional award.

Other Awards. Some plans provide for a minimum cash award but also provide that, if an idea has merit not sufficient for a cash award, a letter of appreciation may be sent to the suggestor. Still another provision is to award merits which are recorded by the secretary and held by the suggestor until he has received a sufficient number of merits to equal a minimum cash award, or until a cash award is made for another suggestion, when the merits are added, at their cash value, to the cash award. Some plans provide for recognition of the value of accepted suggestions in salary or wage adjustments. The consensus, however, seems to favor cash awards for accepted suggestions.

Operation of System. In many plans, provisions are made to keep the identity of the suggestor secret until disposition has been made of the suggestion. This is not absolutely essential to the success of the plan, but as the trend seems to be toward this method, it will be discussed.

Submission of Suggestions. Suggestions should be made up by the employee on blanks provided. They should be sent to the secretary of the suggestion system by company mail so as to avoid delay caused by depositing them in suggestion boxes. Boxes may be used, however, when all the employees are working at a single location, or when they are concentrated at a few locations.

The suggestor should detach and keep the small identification stub, which carries the serial number of the suggestion form turned in.

Consideration of Suggestions. The secretary should, upon receiving a suggestion, make out file and working copies and, in accordance with the nature of the suggestion, index it for reference purposes. He should then transmit a copy of the suggestion to the member of the suggestion committee who represents the department of the company having jurisdiction over the work to which the suggestion refers. This member of the committee then designates on the form, the members of the subcommittee which is to make a study of the suggestion. The number appointed on the subcommittee may vary from one to several, in accordance with the interests involved in the suggestion. The form is then returned to the secretary who sends copies of the suggestion to each member of the subcommittee and follows up the chairman to insure prompt consideration. The subcommittee meets and, after making any necessary study or investigation, arrives at its decision. The chairman of the subcommittee then writes up the decision, which includes recommendations on kind and amount of award, and returns the suggestion and subcommittee's decision to the sponsor or member of the suggestion committee who appointed the subcommittee. If the sponsor does not agree with the subcommittee's findings, he returns this suggestion for further consideration. If he agrees, he initials the form and returns it to the secretary for formal presentation to the suggestion committee.

Final Action by Suggestion Committee. The suggestion committee meets at regular intervals and in special sessions if necessary because of number or character of suggestions submitted. The secretary presents each suggestion that has been returned by subcommittees, and the suggestion committee may accept the subcommittee's recommendations, may increase the recommended award, or may return the suggestion to the subcommittee for further consideration.

Posting Awards. Immediately following each meeting of the suggestion committee, the secretary prepares a list of suggestions on which a decision has been reached, and has this list posted on all the suggestion bulletin boards. He also publishes the list in the employees' paper or house organ. The lists are made up by serial numbers and indicate the action taken; that is, the amount of award is given in the case of each accepted suggestion, and, if further information is needed, this fact is posted with the suggestion number. This added information may be given to the secretary by telephone or may be submitted in writing, identified by the original suggestion number. This provision makes it possible to obtain additional information without disclosing the identity of the suggestor. This also makes it possible to reach the suggestor whose suggestion may not have been given a cash or merit award, but with whom the committee or secretary may wish to get in touch in order that a misunderstanding or misconception of ideas or conditions may be cleared up.

If an audit of the value of a suggestion results in an additional award, many companies make this additional award at some annual meeting of the employees. This method serves to advertise the suggestion plan and thereby helps to keep up the interest. If the company does not wish to provide for secrecy

as to the identity of a suggestor, the serial numbering system can be omitted, and the suggestor can be identified by his name and department. In many places where the secret system has been in operation, the suggestor has identified himself to his superior or the secretary and in some cases has signed the suggestion form.

If the committee organization does not seem desirable, the secretary can work through the executives heading up the various groups of departments. Many companies, however, have found that the committee form of organization has made the plan more effective. In any case, the attitude of management toward the whole plan is more important than the details of organization or the methods of operation.

CHAPTER VI

SUPERVISION

SUPERVISORS: THEIR QUALIFICATIONS AND SELECTION

BY EDWARD DANA, *General Manager, Boston Elevated Railway*

The topic, Supervisors: Their Qualifications and Selection, is the very starting point of the whole program of improving the quality of the supervisory forces. The two divisions of the topic must be treated separately, although they are of course intimately related. Take first the matter of qualifications; what characteristics are needed in an employee who is under consideration for a supervisory position?

There are two points of view here. The supervisor occupies a unique position, in contact with the workers on one hand and with the management on the other. He needs knowledge of the problems of both and sympathy with their aims and plans. This imposes a double set of requirements upon the supervisor—one from the standpoint of the working force, the other from that of the management.

To be acceptable to the working force the supervisor needs certain qualities which are difficult to tabulate but which may be summed up in term *leadership*. It is not necessary to dissect this term for our present purpose, except to note that men like to follow the leader

1. For whom they have affection.
2. Whom they can trust.
3. Who they feel (and feeling plays a large part here) can help them make the most of themselves.

It must be remembered that the individual worker nowadays works in a narrow groove and cannot see his job in perspective and in relation to the big operation of which it forms a part. One aim of management must be to give him as much general information as he will and can absorb, but the chief reliance for the perspective view which comes from trained leadership must increasingly be the supervisor.

It follows, of course, that the detailed qualities will not necessarily be similar in all leaders, but these qualities must comprehend the elements mentioned and they must produce the desired results.

From the standpoint of the management, the supervisor needs in addition to leadership the *ability to manage*. His duty is to accomplish the purposes of his employer with economy, using that term in its broadest sense. Possibly this qualification is a little easier to analyze than the foregoing. Let us see what are some of its characteristics:

1. A willingness to study the organization as a whole, be it manufactory, public utility, or what not.
2. A capacity for analysis and a sizing-up of the vital problems involved in the functioning of the organization.
3. A desire to cooperate with other executives and to look upon the work of each as part of the whole.
4. A conviction that the supervisor's job is largely one of carrying and discharging responsibility.
5. The ability to get things done, to execute plans, to turn out a finished product acceptable to the customer, whoever he may be.

The determination of these detailed qualifications is not a hit-or-miss task, but one of the fundamental duties of management, too often neglected, with resulting confusion and loss later on. There is some risk of going too far in our classification. We all know the difference between good and bad as relative terms. It is comparatively easy to elaborate upon these terms until we reach such a detail of attributes that rarely would a human being be found who could acceptably meet such requirements.

A comprehensive list of qualities desired in a supervisor was compiled with the aid of the men of this rank in the works of the Westinghouse Electric and Manufacturing Company. The items are segregated under three general heads, as follows:

Personal Qualities. Fairness, tact, honesty, optimism, good health, self-control, enthusiasm, sympathy, dignity, firmness, patience, dependability, open-mindedness, punctuality, frankness, poise, unselfishness, sense of humor, courtesy, broad-mindedness, loyalty.

Managerial Qualities. Initiative, judgment, system, courage, resourcefulness, foresight, power of analysis, self-confidence, alertness, decision, progressiveness, perseverance, imagination, concentration, sense of proportion and values.

Special or Technical Knowledge. Material, equipment, economics of production, time study and rate setting, cost and accounting, inspection methods, first aid.

Selection of Supervisors. Any executive who is responsible for placing men in supervisory positions has in mind certain qualifications needed in men eligible for those positions. These may or may not be definitely formulated, but they are in his mind, nevertheless, or he could make no intelligent selection.

When we have succeeded in setting up a definite list of qualifications for supervisors and proceed to the task of selection, we again must proceed upon the assumption of an efficient management with an eye single to securing the very best results.

What we need to strive for in the selection of supervisors is the elimination of the casual, but oftentimes powerful, factors. Some ambitious employees are such good salesmen (of themselves) that they oversell themselves to their employers. Personal qualities which tend to develop friendship may blind the appointing powers to fatal defects in mental and physical equipment.

It goes without saying that friendship, family connections, and, in the utilities, politics must be completely eliminated if real results are to be secured. Such perfection in management does not exist at the present time, but is

certainly not impossible of attainment. As the increased cost of labor and greater use of machinery become more potent factors in successful organizations the necessity for unprejudiced selection becomes more essential.

So much for what should not be done in selecting supervisors; now for the positive side. It is desirable to get the opinions of several unbiased persons regarding an individual who is under consideration for appointment.

A study of personal qualities in connection with one supervisory grade of employees resulted in the following form for the convenience of men who may be asked to express their opinions regarding the characteristics of these employees (see Table I).

TABLE I

Characteristics	Your estimate					
	Very good	Good	Fair	Poor	Very poor	Remarks
Ability to get cooperation...						
Alertness.....						
Courteousness.....						
Decisiveness.....						
Enthusiasm.....						
Foresight.....

Open-mindedness.....						
Poise, dignity, self-confidence.....						
Punctuality.....						
Resourcefulness.....						
Self-control.....						
Sense of humor.....						
Sincerity.....						
Tact.....						
Thoroughness.....						
General remarks.....						

Some such aid as this cannot but prove helpful and stimulating. Estimates resulting from its use, when properly weighed, are valuable in supplementing other sources of information.

Suggestions from a large number of employers as to ways in which employees are picked for supervisory positions all reduce to this common denominator:

1. Get the employees interested in any activities which tend to disclose the qualities previously mentioned.

2. Study them in as many different environments as possible.
3. Get the viewpoints of several people as to their qualifications.
4. Rate them systematically to determine which ones have the highest average of all desired qualities.

In addition to the above, examinations and other tests have their place in connection with the selection of supervisors. Objective tests should be more generally used in connection with promotions.

Why should not candidates for promotion to positions of supervisory nature be required to take written or oral examinations, or series of examinations, on questions skillfully framed to bring out, within the limitations of this method of testing, the qualities sought?

Such examinations might be supplemented with simple psychological tests, to the degree that experience shows the results of such tests to be related to subsequent performance.

Reference should also be made to the value of a general educational program as related to the selection of supervisors. One outstanding result of such a program for supervisors and others is that the participants disclose their aptitudes, and their superiors are given an opportunity to study them with a view to giving the supervisors commensurately increased responsibility.

THE FOREMAN AS MANAGER

BY L. A. SYLVESTER, *Engineer, Stevenson, Jordan and Harrison*

Common Faults of Foremen. Many large concerns have been so preoccupied by their rapid growth, by technical changes in the manufacturing processes, and in meeting competition through new designs and new products, that little attention has been given to foremen. It is common, in plants of this kind, to find foremen growing like weeds, and developing faults which have been forced upon them by the conditions under which they have been working.

One frequently meets the foreman who, having had his position jeopardized by production emergencies in the past, always endeavors to carry a surplus of labor. Perhaps it is not entirely conscious with him, but he likes to feel that he has a certain amount of extra labor "to come and go on."

Then there is the foreman who feels that the importance of his job is chiefly reflected by the number of people who work under him. This type of foreman frequently tries to make a mystery out of the work of his department, and by endowing his work with a false difficulty endeavors to make his job seem very important, not only in his own eyes, but in the eyes of his superiors.

Another fault commonly found with foremen is that of being afraid of their subordinates. Owing perhaps to labor difficulties, or doubt as to their ability to handle men, foremen develop a willingness to give employees practically anything they ask for in order to keep them satisfied. The great bug-

boo of such a foreman is that some day he will come in to work and find his important workers absent. Oftentimes this desire to keep employees satisfied at all costs is accompanied by a hesitancy to say no to any question, and frequently such a foreman will pass the buck to the company management on all problems. If an employee asks him for some privilege, instead of refusing the privilege and giving a satisfactory reason for his refusal, he will blame the refusal on company policy, and express disgruntled sympathy with the worker.

Perhaps the commonest of all foremen's faults is that of being too easily discouraged or turned down by their superiors. Suppose, for instance, that a foreman presents some problem to his superintendent at a time when the superintendent is preoccupied with some other matter, and the superintendent, without very careful thought, disagrees with the foreman's viewpoint. Instead of realizing the situation, the foreman is completely discouraged by such action.

It is quite common for foremen to regard their jobs purely as a series of troubles and fail almost entirely to see the importance or creative side of the work. Foremen are so placed in industry that in many cases there is some justification for this viewpoint. But nevertheless they are performing a valuable function which should be patent to them.

The Foreman as a Manager. Perhaps the simplest way in which the large concern can increase the effectiveness of its organization is by setting up each foreman in business for himself, and thereby duplicating within the large organization those conditions which have proven to be stimulating and energizing in small concerns.

In order to set a foreman up in business for himself and to make him a real manager he must be given certain definite pieces of equipment with which to work. The purpose of these tools is to accomplish two results:

1. To have him know the job and know that he knows it.
2. To instill in him creative imagination, i.e., to make him definitely feel the responsibility for developing and improving the operations under his charge.

The equipment with which the foreman must be supplied before he can start out as manager of his own business is as follows:

1. Daily records of the efficiency with which he uses labor and material.
2. Standardized operations and equipment, developed by the aid of technical assistance when necessary.
3. Financial and verbal recognition of his efforts and accomplishments.
4. Information as to cost of both labor and material, in order that he may judge as to the comparative importance of each.

Records. The foreman's records need not be very elaborate, but they must comply with certain simple requirements. If they are to be of any direct value to the foreman in telling him just what is going on in his department they must cover a short period of time, preferably a day, because in the very nature of the foreman's work, he is continually dealing with a vast multitude of small questions in quick succession. He usually is thinking,

therefore, in short-range terms, and it is almost inevitable that the problems of one day will crowd out of his mind the questions of the preceding day. Not only must his record cover a short period, but it must be prepared and placed at the foreman's disposal promptly. For records to be effective the foreman should receive them every morning, by nine or ten o'clock, covering the activities of the preceding day. To show the foreman a report of his work in the afternoon of the succeeding day will annoy him, and while he may not say so he will wonder why you talk about yesterday when he has so many important problems which are fresh in his mind today.

Just what the foreman's records should contain varies according to the nature of the work he performs, but in essence they should show what the foreman expended in labor and material (if material is under his control), and with what efficiency labor and material were utilized.

Requiring the foreman or his clerk to make out this record means that the speed with which the information is collected is entirely within the foreman's control, and it gives him an opportunity to review each day's record before anyone else sees it. Delays which may have occurred or failures to meet standard of performance come to his attention, giving him an opportunity to think over the reasons for the occurrence, and possible ways to avoid such difficulty in the future. When he submits the report to his superiors he probably does it with comments, calling attention to the deficiencies and offering recommendations as to what action should be taken in order to prevent such delays or difficulties in the future. This has the advantage of putting the foreman on the offensive with his superiors rather than on the defensive.

Performance Standards, Standard Operations, and Technical Assistance. Naturally the setting-up of the foreman in business involves a certain expense on the part of the company, and while there are direct benefits which accrue from it, the greatest improvement from a financial point of view can be made, usually, by standardizing the operations and supplying adequate technical assistance in equipping the foreman's business with the most improved devices, instructing the foreman in their practical use, and also training the workers in the best operating methods which can be determined, either by current practice in other shops, or through time and motion study.

There is one point in connection with the standardization of operations which is always important. Frequently there arise two ways of performing a given piece of work, one suggested by the foreman and one by the staff men. Whenever the merit of the two methods is reasonably well balanced, it is advisable to adopt the foreman's idea, not only because he will be more interested after the installation work is completed, but it will also encourage him to bring out other ideas in the future.

Profits and Praise. Certainly the most important single element, and that element which injects the real life blood into any going concern is the profits. Therefore, in setting a foreman up in business it is essential that some good incentive plan be devised in order to permit the foreman to participate directly in the profits which accrue from his management of the business. The financial appeal is a very strong one, and when it is made to the foreman of a group it frequently has very astounding results. We have had the

experience of installing a group bonus plan in which the foreman participates in a department in which we felt we had cut the cost to a minimum, and were securing the maximum production by means of piece rates and premium rates. We were indeed surprised to find that the putting of the foreman on an economy-sharing basis reduced the overhead of the department, increased the production per man hour, increased the earnings of the direct labor, and made a much smoother running and more satisfactory department as a whole. However, I do not feel that by giving the foreman a wage incentive the company discharges its full responsibility. One of the gravest errors which many companies make is to say little or nothing to the foremen except when something goes wrong. I believe that it is just as important to distribute praise as it is to distribute blame, and I do not believe that it is sufficient to simply set up a foreman in business, offer him a share in the profits of that business, and not notice its accomplishments or commend the foreman. Oftentimes a little praise is far more appreciated by a member of the rank and file than a considerable sum of money.

Cost of Materials and Labor Used. Management is rapidly coming around to the point of view that cost data should be permitted to filter down through the organization. The foreman who is in business for himself should be furnished with accurate cost data with regard to the material which he uses. He needs this first of all to eliminate waste, and to utilize scrap as far as possible. On the other hand, simply urging the reduction of waste oftentimes leads to expending inordinate amounts of labor in salvaging scrap, unless the relative value of material and labor be always at the foreman's command, so that he may know to what extent expenditure of labor is justified in order to reduce wastage of material.

Results. Having equipped the foreman with the essentials which will make him the manager of a business of his own, there remains one very important factor, and that is to set up some record which will show not only to the foreman himself, but to the management of the company, whether his administration of his duties has been progressive or retrogressive.

In conjunction with establishing the foreman in his own business very strenuous efforts should be made to impress upon him the importance of progressive standards. He should be made to feel that what is good enough for this year will not be good enough for next year and that as a result of each year of his interest and enterprise new developments and improvements should be brought out by himself or his subordinates, and that no matter to what degree of perfection he has raised his operation, there is always room for further improvement.

The setting-up of the foreman in his own business should have certain very definite results.

1. It should make for a more responsive organization. The whole effort has been designed to make the foreman know his job better, to make him in every sense of the word a complete master of all the operating details of his department. This presupposes increased self-respect on the part of the foreman, increased interest and attention, and greater enthusiasm, all of which contribute to making the organization more effective, more quickly responsive to the demands of the business.

2. Definite economies should be effected. The work of setting the performance standards and standardizing operation should pay a very handsome return for all the time and effort expended in installation work. The energy and interest on the part of the workers and foreman which are tapped by the wage incentive will produce economies.

3. In addition to the economy and effectiveness of making a foreman manager of his own enterprise is the good will that is created. This good will is by no means limited to a feeling of good will towards the company in the foreman himself, but it extends through his influence among his subordinates and his circle of acquaintances indirectly through the community as a whole, and while good will in the community in which a plant is located does not necessarily mean increased sales, it is nevertheless a definite advantage which should not be overlooked.

4. The last result is the benefit done to the foreman himself—the character-building effect of his better understanding of his job and himself. There can be no doubt but that the foreman who is thoroughly wide-awake and fulfills all of his responsibilities as a manager is actually a better citizen and that society benefits from the upbuilding of the man.

RATING SUPERVISORS

By HARVEY G. ELLERD, *Personnel Department, Armour and Company*

Ratings are and always have been an integral part of organization work and we cannot escape them in some form or other. The defect in the old system of judging abilities and qualifications of supervisors was that consideration was not given to all the qualities and too often judgments were formed on one or two conspicuous abilities or characteristics and the others were not weighed. Very often the person doing the judging attached exaggerated importance to certain qualities and entirely disregarded others. Offhand opinions and personal prejudices played entirely too important a part. Because of these defects, it became apparent that an organized, systematic attempt to value all qualifications, experience and performance was bound to produce better results. It is on the methods and systems that there seems to be such a diversity of experience and opinion.

Armour and Company's first experience in rating supervisors by a definite, systematic method dates back to 1919. At that time, a consultant was called in, and after a lengthy study of our situation, an adaptation of the army rating system was installed. This system, however, did not prove satisfactory and was discontinued after two ratings had been made. No further attempt along this line was made until early in 1925. The subject was then reopened and after a rather lengthy study of the various plans and methods then in use by other companies, a very simple form was adopted.

The accompanying form calls for the employee's name and position, his age and years with the company, then his grading as to five general characteristics.

1. Personal qualities.
2. Intelligence.
3. Physical qualities.
4. Leadership.
5. Trade knowledge.

The person rating the supervisor is asked to indicate his opinion as to what extent he possesses these various qualifications. A check mark is placed

in one of the five squares indicating the degree: exceptional, above average, average, below average or poor. To assist the rater in forming his judgment,

the various factors which in our opinion go to make up and define the characteristics, are shown under each characteristic, and in considering the general characteristic the rater must first consider to what extent the one being rated possesses each of these factors. He then averages all of these, and by average we do not mean arithmetical average, but simply a mental weighing of the various factors to determine the total value on the general characteristic.

For instance, let us take the first item: personal qualities. Properly to judge these analysis must be made on the extent to which the employee is dependable, industrious, open-minded, loyal, tactful, cooperative, and possesses self-control. The average of these estimates will be the weight of his personal qualities. There may be quite a difference of opinion as to whether or not the various descriptive words are directly apropos of the characteristic.

However, they best serve our purpose in their present form, and by having them clearly stated all our ratings are on exactly the same basis. We expect that as time passes improvements will be suggested that will further aid the purpose we have in mind. There is no finality about our present method, but we have found it to be better than our first method.

The next consideration is to grade the employee on his performance; that is on the job he is now on. All men naturally fall into one of three groups.

1. Unsatisfactory.
2. Satisfactory or average.
3. Exceptional.

If an employee is graded as unsatisfactory in his present work then we want to know what other work the rater felt he could do well, what action is planned such as giving another trial, letting him go, or some other suitable action. We also ask what his chief defect is and whether it can be remedied.

If an employee is rated as satisfactory on his present job but not qualifying for larger responsibilities, we then ask what his chief limitation is and whether special training would help him, if so what? Many employees are in this class. They are the pillars that support the organization. No business could operate without a large percentage of such people. On the other hand, of course, they are not promotional possibilities. We have found in a number of cases that a change in the line of work or some special training or experience may help to qualify some of the members of this group of employees for better jobs.

The exceptional type of employee is the promotional possibility who will develop for greater responsibilities. When we find a man of this type we want to know along what line his advancement should be and where, also when he will be ready for advanced duties and what next step is planned in his development.

Procedure in Applying the Rating to Our Supervisory Force. This new rating form was applied first to the supervisory organization of our operating and manufacturing division. The results were so satisfactory that the following year this same rating form was extended to our branch house sales division.

The writer went personally to each plant. Later a member of the personnel department visited the headquarters of each of our branch house sales dis-

tricts. The method of presenting this new rating or grading plan to the operating and sales divisions was practically the same.

The general manager of the plant and the representative of the personnel department rated the various plant sales department heads and assistants. These are the men that the general manager at each plant supervises directly. They also are directed by general sales department heads at the Chicago home office. The ratings on local plant sales departments were checked by the Chicago department head later. The office manager then rated the office force, which ratings were later checked by the general office manager in Chicago.

Consideration of Tendencies of the Raters. Then the plant superintendent at the local plant rated all his department superintendents, foremen, assistants, and such other men in the ranks whom he considered promotional possibilities. I sat in on these ratings, making suggestions, asking questions and watching the tendencies of the man making the rating. Some of these men are enthusiastic and impetuous and in their opinions, their men are apt to be all unusually good men. Other men, more conservative by nature, are apt to rate their men lower. However, it only takes a very brief experience with these men to know their tendencies, and in considering the ratings on their men to know whether they are rated high or conservatively. In this way we know that a man rated as average by one superintendent compares favorably with a man rated as above average by another superintendent.

To check further the opinions of the superintendents as to the plant supervisory force, the general superintendents' organization in Chicago was asked to review these ratings and make any comments upon them that they felt were necessary.

It has so happened for a good many years my own personal experience has kept me in rather intimate contact with the supervisory force of the various plants and as the ratings were being made, I was in position by reason of this knowledge, to make suggestions and to ask leading questions that I felt should be given consideration in the individual ratings. Where I had a difference of opinion based upon contact or experience with an individual, I made special note of that on the rating form. This may have helped to remove possibilities of prejudice, and at any rate, it insured a very careful consideration of each qualification of each man.

At the present time we have made four yearly ratings on practically all of our plants and branch houses. At first it was our feeling that we would make these ratings twice a year. Since we have extended the rating system to our entire personnel and as it takes a considerable length of time to cover the entire organization, we found this to be impractical. Now we have ratings made once a year and find them to be just as valuable and as effective as when they were made more often.

The results from this organized method of judging the supervisory force have been well worth the cost and the effort expended, and I can say confidently that this method of rating is a fixture as a part of our personnel work. I have no doubt that improvement will be made from time to time but, in the main, we find the present method giving us the knowledge of our organization and the control of our personnel that is so very necessary.

Our first rating indicated many weak spots in the organization, and steps were taken immediately to correct these weaknesses. In some instances they had existed for a long time, but the correction of them had been put off. The rating indicated it so vividly that the step was taken immediately. It indicated also the individual weaknesses or deficiencies in certain of our men, and it challenged our thinking to work out methods to correct these deficiencies.

Correcting Elements Lacking in Men. We, of course, realize that there is no possibility of securing men with 100 per cent qualifications, and if we can correct some of the elements that are lacking in the men we have, we are away ahead. Very definite steps have been taken to do this in several instances. As an example of one of these instances: We have a man as a division superintendent in one of our plants who lacks the aggressiveness and punch that he ought to have to become a real leader, and we have felt that he could acquire a good bit of this by contact with other people. We have arranged to put him in a position where he travels to all of our plants on a standardization problem, and we feel that this contact with a larger number of people, many of whom are in positions superior to his, will be helpful in overcoming this deficiency.

Our ratings also indicated clearly the employees who are the stand-bys in the organization. That great army of men and women without whom we could not function, and yet, who by reason of various limitations, are not in line for greater responsibilities. They carry the load of their own work with exceptional ability, and when necessity arises to replace them there is usually considerable difficulty about it.

These facts awakened in the minds of our officials an appreciation of this group that never had been indicated before. We have to have privates in industry just as we do in the army, and we cannot have people all of whom are qualified for positions of greater responsibilities.

It indicated to us, too, those persons who are promotional possibilities and just what was necessary to develop them for bigger jobs. A number of men, upon the making of this analysis, were found to be ready and fully equipped for better positions, and wherever possible advancements were made almost immediately.

There are others who may require additional experience on their present jobs, or they may require specialized experience, and the picture presented by their rating was so vivid that wherever possible steps have been taken to supply that experience that may be lacking.

About the time that we completed our first rating it became necessary to man two new plants which had recently been purchased by the company, and in doing this the ratings were used to very good advantage, and they enabled us to make selections that we otherwise would have made by relying upon memory or general impression. It is strange what insignificant things form favorable or unfavorable impressions of men, and it is our hope that, with the use of a method of this sort, the thoughtful consideration given to all qualifications and characteristics, will overcome hasty impressions which so frequently are incorrect.

One does not want to give the idea that there are no weaknesses in our method; on the contrary there are many of them. The fact that so many of

these characteristics are not subject to objective measurement is a matter of concern. If we had some measuring stick that we could definitely apply to men as regards abstract qualifications, it would be a happy situation indeed, but items such as judgment or dependability or cooperativeness or self-control, are not things that can be measured, and we simply have to accept an expression of opinion upon them from the person who is in close and intimate contact with the man being rated. The fact, too, that we supervise these ratings so closely assures us of getting a similarity of definition. We are certain that all of our people are defining these qualities in the same way, and by doing that their opinions are based upon the same factors. They are of course only opinions, but when expressed in a definite way along a prescribed line, they become valuable, and especially so when they are carefully supervised by a single individual. They are far more reliable than if we relied upon each individual rater to make his rating without such supervision.

Measuring a Man's Ability. As to performance we can have a definite measure of man's ability. We know from his production costs, quality of his product, and the stability of his organization whether or not he is coming through, and we have a measure that we can apply on them. As far as the intangibles are concerned, we have to accept them as being matters of opinion.

In several instances men have been recommended for salary increases or for promotion, whose ratings did not indicate that they are deserving or are the right type. In some of these cases when we have called this to the attention of the person making the recommendation, we have encountered stubborn objection and the statement that the rating is wrong. However, it has only taken one or two instances to indicate that the rating must be accurate or difficulty is going to be encountered in putting through recommendations that are inconsistent with it.

In one specific case a plant superintendent definitely rated one of his foremen as having ability to become a division superintendent. At the time the rating was made I questioned it very carefully because I knew the man well and did not feel that he possessed the necessary qualifications. It so happened that a little later there was a vacancy at this plant and this superintendent recommended another one of his foremen to become a division superintendent. When we asked him why he did not take the man that he had rated the highest, his answer was that he had changed his opinion of him, but a careful analysis of the situation led us to believe that he had rated the man highly in order to get him out of his plant, and that when the opportunity was presented where he might have promoted him, he would not do it under any circumstances.

Cases of this sort are isolated instances, and there may be such a temptation on one or two occasions, but it will not happen frequently.

We also encountered one or two instances where high ratings were given to men evidently for political reasons. These men in some cases, were relatives of officials at other places, or were reputed to be protégés of certain officers. This weakness will always be displayed, and in considering the ratings as we are using them, we have to make allowance for it.

The attitude of mind with which this present rating plan was received by our old timers is of interest. We have been in business now over sixty years, and we have a lot of hard-boiled supervisors that have come up through the ranks. They are not easily sold on any new fangled ideas. We anticipated that there would be a good bit of joking and possibly some objection to it just as we encountered in our first rating scheme, but we were agreeably surprised. It was received seriously, and was apparently established in the minds of most of these men as being a very necessary adjunct to our business. One old-timer said to me, "It's about time we had something of this sort. Now we are going to be judged for what we know and not for whom we know."

Desire for Better Valuating Methods. Of one thing we are definitely convinced, some method of valuing supervisors is essential, and the more simple that method can be made the more effective it will be. In any improvements on our present method we shall lean over toward the side of simplicity.

This conclusion was brought home to us because of the sincere conviction that ratings must, to a large extent, be gaged upon the capacity of the persons who are to do the rating, and they must be expressed in the terms and language which are commonly used by these people. They must not be burdensome, lengthy or involved, or there will immediately be a lack of interest if not a definite resistance.

If we received no other return from our rating method than the fact that the heads of the various divisions of our business made a careful analysis, inventory and valuation of their organizations, it justifies itself in every way.

We know, of course, that this is only one of its valuable features. The inspirational effect upon the organization and the hopefulness that they will be given their opportunity to break through is another value that is immeasurable, but it is there to a wonderful extent.

In the past we had felt rather complacent in the thought that we had means of keeping good people before us and not permitting them to be buried, but our ratings indicated clearly how weak we were in this respect and how necessary a frequent inventory of our manpower was if we were to keep before us constantly the people with promotional possibilities. I can say without hesitation, that with us ratings of our supervisory force are no longer an experiment. They are a fixed and definite part of our personnel policy.

WOMEN IN SUPERVISORY POSITIONS

By **E. H. LITTLE**, *Assistant Supervisor, Industrial Relations, United States Rubber Company*

Before entering upon any discussion of the subject of women in factory operating positions—their selection and training, their handicaps and contributions—one reservation must be made. Discussing the subject at all violates a principle laid down for myself and runs counter to advice given others on more than one occasion, namely: Ignore the fact that you are a

woman. Assume that if you have anything to offer it will be accepted on the basis of you as an individual; neither that it will be refused because you are *not* a man, nor that it will be received because you *are* a woman. This is women's sound and logical approach to their problems in industrial and business life. I should like to leave it at that, but so recently have I heard a man register his objection to the masculine woman that I hasten to forestall any possible interpretation of the above to mean that I am advocating woman's attempting to copy man's habits or mannerisms. That is suicidal—principally because it is a *copy*. True sincerity and freedom from affectation of any kind are first requisites for a woman's progress in the industrial field.

Scientific studies have repeatedly shown that individual differences between men, and individual differences between women are so much greater than general differences between men and women that we must conclude that these general differences are themselves in greater measure a result of training and environment than of inherent differences between the sexes. If this is admitted the subject really resolves itself into: What is the difference in the education, training and experience of women holding positions of forewomen or assistant forewomen in factory work, and men holding similar positions?

Industry is not a new field for women of the type we find in factory supervisory jobs. Domestic service and factory work have been open to women longer than any other lines of work. In the days when these two fields offered women their only opportunities of earning a livelihood outside their own homes, the question of unfavorable comparison of forewoman with foreman was far less frequent than today. I say this on the basis of my observation of the type of our older women supervisors that are passing on to our pension rolls, and also from talks with older superintendents. From them I hear stories of the old contract system in industry; that women, as well as men took out those contracts; and that they held positions that are now held by men. What is the difference? The answer lies in the new and better openings for women. With the change of public opinion toward education for women, factory work, because it did not require an education, took unto itself a stigma little better than domestic service. The fact that supervisory positions in factory work call for patience, persistence, resourcefulness, and leadership, plus skill, in short for character, which will always be an attribute higher than education, was not sufficient to offset public opinion's deprecatory attitude toward the factory girl. And the inevitable result is to lower the calibre of the group from which we must select our forewomen and assistants.

Four Classes of Women Workers. It has been the practice, even more generally with women than with men, to promote from the ranks. The rank and file then as the source from which we draw our supply of women supervisors cannot be passed over in our attempt to analyze the forewomen of today, or of tomorrow. Whom, then, do we find in the rank and file? They may roughly be grouped into four classes: the young girls, the unmarried older women, the married women, and the widows.

In the first class are the young girls who have gone into industry direct from grammar school, or as soon as they can get working certificates. Factory

work is their temporary avocation preceding their vocation of matrimony. In time they may have to return after an unsuccessful venture in the latter field—but who of us anticipates lack of success—at least when we are under twenty. Such a characterization of this particular class intentionally suggests the impermanence and lack of stability of the young factory worker when viewed in the light of a possible supervisor. Even as I write this, I am reminded of some striking exceptions. In justice to these, I must make the point that young men of the same age, satisfactorily holding down supervisory positions, by comparison, are quite conspicuous by their absence. This difference is doubtless due to the fact that boys mature more slowly than girls, who, having already assumed home responsibilities, respond better to those placed upon them by industry.

In the second class we find those of this first group, who, as the years pass, find the possibilities of their prospective vocation of matrimony fading away, and its place being taken by their avocation. Very frequently the reasons back of this change of point of view are dependents in the home circle, a widowed mother or an invalid father. For any one of a number of reasons, she *must* continue to bring home her weekly pay envelope, and so she settles down to life as a factory worker.

In the third class is another group, part of whom belonged originally to the first class—that is, the married factory workers. There are those who have found matrimony an unsuccessful venture; the husband through sickness, accident, or general incompetence cannot support the family, and the wife must contribute her share. Added to the disappointment of realizing what life holds out for her are home duties and responsibilities. Even if the factory makes the mistake of selecting such a worker for promotion, she usually may be counted upon to refuse this further responsibility.

Another group of this class is the girl who voluntarily keeps on working after her marriage. She does it for one of two reasons. Either she does not know what else to do with her time, or else she and her husband are working for some particular objective—an automobile or a home. Whatever the reason, her continuity of service cannot be depended upon. Finally in this class we find the married, and frequently un-Americanized foreigner. Regardless of husband's income, and children needing her attention, she yet expects and is expected to contribute her weekly wage. For obvious reasons she is poor supervisory force material.

In the fourth class are the widows. They have two probable drawbacks when considered as possible supervisors. In addition to the fact that they are likely to be struggling with the very insistent home demands of growing children, their tendency is to look upon their own lives as past and finished. They, therefore, lack the "pep" and initiative that make for leadership.

Source of Successful Supervisors. We return then to the second class as the source from which we shall find that most of our successful women supervisors and forewomen have come. These are the unmarried women who have stayed on in industry. If one may generalize, we may sum up their qualifications somewhat briefly in this way. Having entered industry direct from grade school, they are lacking in general education. Having had long experience in the industry, they are skillful workers. Having worked

for years in the same place, they are narrow in experience. They have been promoted on the ground of their high quality workmanship, good attitude and all-round superiority to their fellow workers. In native ability, then, they are above the average, but lacking opportunities either of education or breadth of experience, they are handicapped when they come to assume the wider responsibilities of directing the work of others, and of developing the qualities of leadership. Here then is the background, education, training, and experience of the average factory forewoman. If, by analyzing this education, training and experience into their probable results, we can find the reasons back of the unfavorable comparison of women with men in factory operating positions, this analysis should suggest the paths which lead to the solutions of the problem.

The Forewoman's Handicaps. First, *lack of education and experience.* Right here, I put myself in the position of any one of upwards of a hundred women supervisors with whose problems I am intimately acquainted, and I try to think out what would be my obstacles to proper functioning as a member of the management, and I believe that my lack of education and experience, which in itself would limit my possibilities for promotion, whether I were a man or a woman, would also be back of many of the criticisms of me as a supervisor. It would be back of the charge that the forewoman does not get the management's point of view, and does not understand the cost phases and business principles of factory operation. It would account for lack of self-confidence; a hesitancy to accept responsibility, and to make decisions; and the failure to criticize and make constructive suggestions for the betterment of the department. The narrowness of experience would, in itself, be reason enough for certain lacks of mechanical knowledge, of resourcefulness, and of failure to see things in their proper proportions with a consequent overemphasis of details and "little things." All these charges I have heard brought against women unqualified—not against women who have been limited by conditions over which they had no control.

Second, *lack of incentive because of lack of promotion possibilities*—even for the exceptional forewoman. How many rungs are there in the factory girl's promotion ladder? Worker, inspector, forewoman—what then? How many have taken the next step up? To tell a forewoman that if she does a good job she may be promoted, somewhat closely resembles telling the small boy that if he gets his lessons he may some day be President of the United States. When the factory worker has become a forewoman she has arrived, and there is nothing ahead. Let any one of us take that fact and think it out to its logical conclusions. Can we not see in it reasons back of some other objections to women as factory supervisors? When incentive is gone, the hard things in the day's work become harder because they are not only today's work, but tomorrow's and next year's, and the temptation to duck them comes just that much stronger. "Women don't like to do unpleasant things." Is it surprising? When a man does an unpleasant thing well, in the back of his mind lurks the possibility of the reward of promotion. There may be more unpleasant things to be done on the next job, but they won't be the *same* ones, with the *same* people. Then, we hear that the woman is more emotional; she gets upset. Why not? What does she lose by so doing or gain by

refraining from her tears? At this point I want to ask another question. If we wish to deny, to woman, woman's privilege of tears, do we, at the same time, extend to her man's privilege of "cussing" or do we expect her to be wholly superior to men in this respect and require no form of emotional outlet?

With the lack of promotion possibilities for women, we see a vicious circle operating to her disadvantage. Because management has ruled out the possibility of her promotion above the position of forewoman, her job is too good to waste on a woman. One of the arguments for putting men on jobs supervising women workers is that these jobs are good training places for those higher up, therefore they should be filled by young men being trained for future executive positions.

Third, *for the same job a woman, regardless of how well she fills it, receives less remuneration than a man.* It would hardly be surprising if this fact did not reflect itself in her attitude toward her work. Woman has a strong sense of service, but even as she serves she says to herself, "Now don't be a fool, you won't be paid for that extra effort," so instead of incentive for exercising initiative and assuming responsibility, comes the deterrent of unequal pay for equal work. To a group of factory clerks was put the question: "Would you like the job of section foreman in this factory?" Their answer was, "If there is a chance to make the money that goes with the job, we're willing to work for it."

Fourth, *a woman has more definite home duties than a man even though she may be the breadwinner for the family.* It is the rare exception where the woman supervisor or forewoman does not have to meet comparatively heavy demands in her home, as well as at the factory. This, of course, is a condition over which the factory has no control. Frequently it does account not only for her lack of initiative—too often that is going into the solution of home problems—but also for the fact that the long factory hours present a physical drain greater than she can handle. Facts and statistics prove that here, women in general suffer a real handicap as compared to men; but in addition to this general health handicap the forewoman who has remained in industry as a means of meeting those home responsibilities frequently has two distinct jobs: the factory job and the home job. This unquestionably affects her efficiency as a member of management.

Qualifications for Promotion. These are the handicaps of people with home responsibilities, who tackle a supervisory position, lacking education and variety of experience, and for whom little incentive is provided. They would be the handicaps of a man similarly situated. It is these handicaps which do account in large measure for the arguments brought up against placing women in such positions. I am more than ever convinced of this when I review the conspicuous success achieved by some of the forewomen of my experience. One is a college graduate, another whom I think of is a graduate of high school and a third lacking formal education has its equivalents in family background and standards of attainment. With these particular women, as with others I could mention, there is an assurance and confidence in their handling of workers that bespeaks a job well done. They execute that job with a "finish," that in my experience could characterize only one foreman supervis-

ing a group of women factory workers. In other words the problem resolves itself into finding in our rank and file the woman with the proper qualifications for promotion. Discuss the question with an open-minded foreman or superintendent, and his insistence on the "right type" will again bring home to us that it is a question of individual differences rather than general differences between men and women. So our problem of women in the supervisory force has reduced itself to the problem first of recruiting, then of selecting and finally of training. In those three words—recruiting, selecting, and training—I realize, to use a classic expression, "I've said a mouthful." In fact I am afraid thus far I have painted a rather discouraging picture. With that in mind I shall devote the next section of this paper to comparing the assets and liabilities of men and women supervising departments in which female labor is employed for the purpose of determining whether the benefits to be gained will warrant the effort entailed in recruiting the right kind of women supervisors.

While there are still factories employing large numbers of women workers who do not consider it practical to promote women to responsible supervisory positions, there are many others with whom this has always been a policy and they believe that this policy nets them results which can be achieved in no other way. What then is the contribution they expect from these women which they would not get from men in similar positions?

A Woman's Assets and Liabilities. A woman's greatest contribution lies along the lines of her personnel relations with her subordinates. She understands them better than does the man. In fact, I am inclined to believe that the average man prides himself on his inability to understand women. It is just that lack of understanding which will fail to unearth many of the causes of friction which prevent a smooth running of departmental machinery. Unhappy love affairs, problems of domestic relations, sickness in the family resulting in sleepless nights can all affect production. Cases of this sort as well as problems of personal hygiene are more readily discovered and better handled by a woman than by a man. A woman can give her workers a personal interest and encouragement which may in itself increase earnings and decrease costs. Usually having been promoted from the work itself she has a better understanding of the details of production problems than would a foreman. She knows what may reasonably be expected in the way of workmanship and production. When she is a good supervisor less is "put over" on her. With her, tears are no weapon. Finally, she can present to the management the women workers' point of view. She becomes the "friend at court," and her existence is even more important than the concrete things she brings to the management's attention. In these days of a more adequate evaluation of the importance of human relations the opportunity to cash in on a contribution such as I have outlined here should not be underestimated and cannot be overlooked.

These are her assets in dealing with women. May she not also have some advantages in her dealings with men? Judging by my own experience she has. With regard to her superiors, when she deals with the better type of foreman and factory executive she receives a courtesy and a generosity which manifests itself in an attitude of helpfulness and cooperation and which fre-

quently gives her a head start. The less advantage she takes of this conventional deference of man for woman the more it will be granted her. With the occasional man whom she finds among her subordinates she frequently has less difficulty with regard to discipline than would a man. The difference in sex supplies just that barrier which simplifies the job of supervising another person. Certainly it has been our experience that when due to changes of production it has been advisable to use temporarily some of our women supervisors with male workers they exacted and obtained higher standards of performance than the usual man supervisor.

The forewoman has some handicaps in her dealings both with men and with women. This must be recognized. First, in her contacts with women. The handicap that I most regret to admit, is the attitude of other women. Women have taken their place in affairs outside the home for too short a time to have developed the class consciousness and class loyalty which make for recognition of leadership by one of themselves. Moreover they lack the boyhood training of gang membership and hero worship which teaches both leading and following. Hence entirely too frequently do we hear a woman say "I don't want to work for a woman." This will be corrected only as women supervisors demonstrate that they are the kind of persons for whom people like to work, and that is women's problem and more than ever the challenge of those of us on whom industry and business have placed the greater responsibilities, and one which quite frankly I, personally, accept very seriously. We ask the help of men in just one respect: Please don't capitalize that remark when you hear it, but instead won't you analyze the objection down to the particular quality of the woman supervisor to which the woman employee is objecting, and see if it is a fault for which men may be wholly exonerated. In other words is it really characteristic of women, or rather characteristic of a poor supervisor. And don't be misled by vocabulary. I have frequently wondered just what was the essential difference between jealousy among women and rivalry and competitive spirit among men except the difference in the connotation of the terms. Certainly the products of the two emotions are strikingly similar.

The Problem of the New Forewoman. At this point it may be well to point out that one of the reasons back of the popular assumption that women object to a woman supervisor is that a new forewoman has a more difficult problem to face than a new foreman, both supervising female employees. The woman invariably will have been promoted from the particular group she is asked to supervise. In the first place, some of them remember when she was a learner, they all probably can think of some mistakes she has made. In the second place, to be a good supervisor, and to avoid the accusation of favoritism and partiality she must establish a difference between herself and her workers; she must have no intimate friends among the group. At the risk of being called "stuck-up" and conceited, she must change her relationship to her former coworkers from being one of them, to being one over them. For the man, the difference in sex provides the barrier which automatically eliminates 50 per cent of the new supervisor's obstacles. This then is a problem of careful training and wise encouragement, both of which can better be given to a woman by a woman than by a man.

So much for women's handicaps in dealing with women. What problems do men present to her? Probably because she seldom has to deal with men in any number among her subordinates, they in my experience present small difficulty—not so her superiors. Here her greatest handicap lies not in their reluctance to accept her as an individual, but rather in their tendency to treat her on the basis of her being a woman. As such, "she is a peculiar animal, unaccountable, she doesn't reason and can't understand, therefore why explain? Better save your breath!" So with few explanations, she is given instructions instead of policies. Then when changed conditions have invalidated the instructions, she is blamed for lack of results and the whole situation is dismissed with the all-inclusive explanation "just like a woman."

Woman does not have an easy course to steer to win the confidence and respect which will gain for her a man-to-man treatment. With wisdom and foresight she must avoid on the one hand the Scylla of being an "easy mark" who will give way under opposition; and on the other the Charybdis of being a "crab" and a "crank" whom the foreman fears will "get started." If I could endow her with a magic gift to aid her with her problems it would be a good stiff backbone well coated with a sense of humor. I would give that backbone such a thick coating of sense of humor, that the other fellow would not know that the backbone was there until he woke up the next day to find she had had her way when he had thought the decision had been his.

A Man's Assets and Liabilities. At the risk of overemphasizing the problems of the woman supervisor in a factory I have tried to deal faithfully with all those objections which at various times I have heard brought up to her discredit and disadvantage. Now the time has come to consider the foreman in his relations to his women workers. I have already admitted that convention and precedent give him an advantage, particularly in the class from which factory workers are drawn. Here man is much more dominant than in the group where the girls as well as the boys of the family take for granted the opportunity or privilege of a college education. This conventional difference is, I believe, the basis of the foreman's advantage, and he himself will admit he has handicaps. He knows that the undesirable factory girl will, and any of them can, take an advantage of him that would not be attempted with a good forewoman. He cannot try to discover the real truth back of many a situation. Moreover before tears he is helpless, and tears are not always what they seem. As a means to some ends desirable to the factory girl they are more effective tools than the equipment with which the management provides her. We hear much of the value of personal interest shown in one's workers and yet every good foreman knows that he cannot show his interest except at personal risk to himself, and the younger he is the greater the risk. These handicaps he will readily admit. In addition, he cannot know his workers well enough to deal with them as individuals. I am quite sure that this lack of understanding is a real obstacle when he comes to select a supervisor. He knows his workers for their machine-like qualities, for their ability with the materials in his department. He must choose his supervisor for her human qualities, for her ability with the workers in the department. It is a trite remark to say that a good workman is by no means necessarily a good supervisor. An assistant forewoman

must be chosen for her ability to win the confidence and support of other women, and this ability is rarely demonstrated by her success in attracting the attention of the foreman, and yet it is upon this basis that the minor woman supervisor is usually selected.

Management's Attitude to the Woman in Supervisory Capacity. This brings us to the point of management's attitude to women holding supervisory jobs in a factory. It is a very important one. The success or failure of the women depend more upon this factor than upon any other. Foremen reflect their superintendents and works managers. If the company officials assume that women's progress is limited, if they are skeptical, she will be given only half-hearted support and her failure is a foregone conclusion. What progress she makes will be resented both by the men and the other women and the conclusion of the whole matter will be "women don't like to work under her and men won't, and that's all there is to it." This with an air of finality that dismisses the question as a closed proposition.

Even where the higher officials have the right attitude towards women, a difficulty frequently lies with the foreman. In general I would say that the foreman does a better job with his workers than with his assistants and a better job with his men than with his women assistants. He not only fails in the sufficiency of his explanations and in taking too much for granted, but when his assistant forewoman falls below his expectations he blames rather than criticizes her. He assumes she is as she is and cannot be changed. The fault should be laid at his door not hers. Developing his assistants is his job. When he does not do it, the forewoman cheerfully goes along believing she is giving satisfactory performance when she is capable of doing a very much better job. The same foreman who will give to his young assistant an honest appraisal of his successes and failures cannot be counted on to deal with his assistant forewoman in the same straightforward way. This is one of several missing links in the forewoman's training.

The Suggested Solution. Very briefly I should like to suggest the solution of the whole problem—the means to the end of more and better women supervisors in our factories.

I am assuming that we agree that where a factory is employing any considerable proportion of women workers that it is desirable to have forewomen and assistant forewomen of the right type in the supervisory force. Success in obtaining the right type lies along these lines.

First, management must adopt a constructive policy toward the problem. It must make the effort to recruit the kind of worker who will make a good supervisor; it must follow-up the workers closely enough to be able to know and recognize promotion material. Having made the first promotion it must be in a position to give the careful training and coaching that reduces mistakes to a minimum and turns the unavoidable errors into object lessons from which encouragement for future success may be drawn. Management must share with minor as well as major executives its problems and policies. Management must realize that only to the extent that the supervisors, down to the least one, can fairly and adequately represent it to the workers, can management consider itself intelligent. This has been repeated, regarding the foreman, so frequently that I almost hesitate to reiterate it here. But the point

that has not been made equally clear is that this is just as true of the forewoman as the foreman. Therefore my constructive policy is, treat her as you would treat a foreman. The law of supply and demand that has kept down her wages, should not be assumed to apply to her training.

The second is the logical conclusion of the first. If management hopes to realize the best results from its women supervisors, there must be in the management a woman executive to whom the works manager or superintendent can talk as he would to a man. Upon such a woman should be placed the advisory responsibility of developing the women in the supervisory force. Management should look to her to help execute the policy outlined above so far as the women are concerned. To the women she will be an evidence that women's contribution is appreciated and recognized, and that promotion above the rank of forewoman is not beyond the realms of the possible. Such a woman can spur on the other women to motives for success to which only a woman can appeal. To such a woman, the forewomen will not hesitate to tell their problems and to admit their lack of knowledge and misunderstandings. I could illustrate this repeatedly from my own experience. I feel so strongly on this question of the necessity for a woman executive that I would say to any factory manager who is not satisfied with his results from his women supervisors, "If you haven't a woman on your staff who is thoroughly familiar with your policies and who has been given the responsibility and is capable of developing the women in the supervisory force, you do not know what latent power lies hidden in your organization."

CHAPTER VII

TRAINING AND EDUCATION

THE TECHNIQUE OF TRAINING ON THE JOB

BY H. G. KENAGY, *Assistant Manager, Life Insurance Sales Research Bureau*

The investigator who starts out today in search of training methods which can be dignified by the term "technique" is apt to declare, after his first excursion into the field, that he has been looking for something which does not exist. He has asked executives, department heads, field managers, foremen, personnel managers, and educational directors for descriptions of their training methods. They have told him, with variations, that they have training courses, job instruction manuals, even job instructors, but that they have no standard plans for making sure that the instruction is given in the best possible way. In fact, many indicate, though they do not so state, that they do not have training on the job. A few frankly support the policy: Give the beginner a chance to learn and then let him sink or swim; if he has the right stuff in him, he will survive.

Putting the Responsibility on the Learner. At the risk of being considered a captious critic, I shall quote a few descriptions of training methods which came in response to a request for information about methods of teaching on the job. Since I wrote to well-known companies, these examples are taken from the practices of our very best people, so to speak. If they do anything about the technique of training, they did not consider it important enough to mention.

A competent pressman, accustomed to teaching, was assigned a few presses, and young men over twenty-one years of age were selected and given intensive training on the machines, the class of work being such that each one has a chance to learn the operations. Carefully prepared lesson sheets are used by the students and classes are held for special instruction and to discuss any questions that may arise. The plan is proving satisfactory and enables young men, willing to be trained, to learn a high-priced trade in a comparatively short time.

This was one of the best responses. It is good as far as it goes, but it is silent on methods of instruction on the job. And one fears that the silence is due to lack of attention to the fine points of instruction. These are in all probability left entirely to the particular pressman in charge.

New men are usually started on the lowest job in any sequence or group of jobs, and learn their jobs largely by imitation and by word-of-mouth instruction from the other men in the gang or from the foreman.

Then, if the learner, be he a new man or one longer on the job, has ambition and initiative, he is constantly trying out on the job ahead, so that it frequently happens when the next job ahead is open, he is ready to move up to that job . . . Whether the man gets the chance (in the rolling mill) depends on the roller. If he is a real foreman, he gives his men every possible opportunity to learn the job ahead. If he is not this kind, his men are the losers.

Even if all the foremen in this steel mill were 100 per cent anxious to see their men advance, I wonder if that would guarantee that each man would develop the best possible skill in the shortest possible time.

This from an office organization:

Our plan is to place the new employee on a given job under the personal instruction and supervision of an experienced worker on the same job, giving to the experienced worker instruction as to the training to be given. This experienced worker comes directly under the close supervision of the assistant superintendent. It is all hand training, as we have no outlying course . . . We do have a manual of office practices which deals with the technique of their jobs. With this as a text and the experienced employee (most frequently a floorlady or a head correspondent) constantly on hand to supervise and direct, we manage to attain quite a high degree of efficiency.

I do not doubt this last statement. Careful selection and high morale, which I know are present in this organization, will work wonders. I wonder, however, how many new employees are learning inefficient working habits under the tutelage of "experienced" workers who perhaps worked out their own methods by the trial and error system years ago.

From a textile factory comes a description of "our most successful plan of training apprentices":

We give one apprentice to a journeyman. We pay the apprentice, and the journeyman is entitled to all the work that the apprentice does for a period of about three months, in consideration of the time that it takes the journeyman to train the apprentice. If a journeyman is really conscientious in training a boy, this we find is the better plan. Sometimes, however, a journeyman exploits the work that the apprentice can do and will keep him on the task that produces the most for the instructor . . .

As soon as the apprentices are able to go by themselves, they are put on a task basis, but we have men who devote their time to watch the boys so that they do not get into wrong habits of work. The boys may ask these men to assist them whenever they need assistance.

The intimation here is that the chief problem is to find conscientious journeymen. How many school children have had their natural curiosity and desire for knowledge blasted by supposedly trained and thoroughly conscientious teachers?! Besides, the attitude here seems to be wholly passive. Instead of watching the boys to keep them out of bad habits, how much more logical it would seem to teach them good habits from the start.

From a motor company we hear:

"There is no standardized procedure in this company for training on the job. One of the most common methods is to place a new employee alongside of an older employee doing similar work, the older employee giving most of the information and instruction needed . . . Another method . . . is simply starting an employee in and gradually increasing the responsibility until the new employee is carrying the position for which he was employed."

Finally, to bring to a close a string of quotations that I could continue to unwind, a machinery corporation that spends a great deal of effort and money on training various classes of its newer employees says:

In connection with all our training plans and activities, we believe that the men who are really desirable and who will represent real possibilities for the corporation are those who, given a reasonable opportunity to observe, ample facilities to clinch their observations by practice, and all possible information, can stand on their own feet.

The old theory that "you can't keep a good man down" has been thoroughly and completely wrecked and yet undoubtedly the men with initiative will always outrun those who lack somewhat that excellent quality. Certainly they will take training better than will their fellows. But initiative, along with other qualities, can be developed by training. Why isn't it good economy to see that *all* workers get the training they need?

I should like to continue this recitation by citing some training methods used in connection with salesmen. Unfortunately, with few happy exceptions there would be a monotonous sameness in the base structures, though often with striking variations in the ornamental superstructures. As a general rule we find product instruction given in classrooms, or through sales manuals, perhaps accompanied by some practice selling, some talks on salesmanship, followed by a short period of observation in the field with an experienced salesman.

Training "by Absorption" Does Not Build Correct Work Habits. These excerpts give evidence of a serious undervaluing of the possibilities of training on the job, and little comprehension of the waste in manpower which is implied in training by absorption, depending on the initiative of the worker and the interest and natural teaching capacity of the worker's superior, or of the worker being observed. The assumption that correct habits of work will form naturally from observing the acts of another, even an expert, when followed by the requisite amount of experience, is entirely baseless. The late Frank Gilbreth found that of the eighteen customary movements used in bricklaying—a craft 6,000 years old—no less than thirteen were wasted and valueless. Leffingwell has shown that few clerks know the right way to affix a postage stamp on an envelope. The untrained clerk will rarely be able to affix stamps at the rate of more than 1,000 an hour—about 16 a minute. A clerk trained in the one best way, however, can easily affix 84 per minute or 5,040 an hour without appearing to be doing the greater amount of work. Yet how many office managers continue to assume that office work is simple, requires no training, and that work habits are of no particular importance.

Perhaps training by absorption works best of all in the development of supervisory material, for here a great deal of care is generally exercised in selecting those to be trained, and intelligence, initiative, and ambition are usually present. Certainly the plan is endorsed as highly successful in many important companies. One of the Standard Oil companies, for example, makes much of its six-step foreman training plan. The student progresses, during a period of about three years, from routine work in staff headquarters, through special assignments, teaching apprentices, mastery of work in one department, assisting a foreman, etc., to supervisory tasks covering several departments. The published description of the plan carries such phrases as: "Is assigned such duties as will make him familiar with"; "the second period is to teach him company policies"; "he is placed under direct supervision"; "he is instructed in handling men"; "he attends foremen's conferences," etc. The emphasis indicates that the responsibility for proper progress is almost entirely on the student. There are many examples of carefully worked out training plans—as far as logical steps in progress, well-prepared training material, and systematic check-up are involved. In countless sales organizations men are started in the office or factory, promoted, on show of "promise," to service men or junior salesmen, sent to training schools or enrolled in correspondence courses, sent out to observe experienced salesmen at work, and then given territories of their own as "trained" salesmen.

Undoubtedly, most seriously-conceived training plans have excellent features, yet we look in vain for any indication that the possibilities of training on the job have been realized. Attention *may* be ample; but if so, it is odd that it has not been mentioned. There is little to suggest that the methods of instruction have been given any thought; that any effort has been made to insure that the student learns what he should in the easiest and quickest way. Perhaps the same or even better training results could be achieved in one-half the time; perhaps the mortality among students could be greatly reduced. Until we give intelligent attention to the technique of training we cannot begin to be sure that our results even approximate the possibilities.

Training "by Intention" Puts the Emphasis on Instruction. Training by the absorption method must give way to training by intention accompanied by standardized technique in instruction. Such training involves, first of all, the familiar job analysis to determine the teaching content of the trade or the job. This job analysis, by the way, as the industrial engineers remind us, should not be a mere catalogue of duties as ordinarily performed, but a statement of the proper method of performing specific tasks. From a study of the tasks to be done we can group into blocks the tasks of similar difficulty and arrange the tasks within each block in the order of learning difficulty. C. C. Via describes a device known as the "progression factor table" to insure an orderly progression of tasks varying from simple to complex.¹ The analysis also shows the information content of the job, and indicates at what

¹ Lecture 4, 1927 to 1928 series, *Foremen's Lectures*, Newport News Shipbuilding and Dry Dock Company.

step in actual manipulative operations each element of knowledge should be taught. The time to teach a fact is when the actual need arises on the job.

Training by absorption assumes that the beginner picks up the knowledge he needs from studying books, or in formal classes, or by observation and questioning—an assumption far from correct. Training by intention assumes nothing. It makes sure that the teaching points of each task are listed and then teaches each point as it is needed.

This is a fundamental point for good training technique, though the theory of job analysis is now widely accepted. Dr. W. W. Charters, Dr. John A. Stevenson, and many others have shown the necessity of following through the four steps of (1) demonstration by the trainer, (2) trial by the beginner, (3) correction of mistakes, (4) follow-up, repeating the first three steps, until correct habits of work are formed. There are some points which, though given lip service, do not seem to be followed in actual practice.

Telling Is Not Teaching; "Bawling Out" Is Not Correcting Mistakes. Many concerns which claim to be training on the job are making the mistake of assuming that showing a worker how a job is done is training him to do it. *Demonstration, alone, is not teaching, any more than telling how is teaching.* If it were, then the most skillful operator or the most finished salesman would be the best teacher. It has been clearly shown many times not only that demonstration is but one step in teaching, but also that the methods of demonstrating are of the greatest importance. In the field of insurance selling we used to believe strongly that the only real way to teach a new man was to have him do joint soliciting—that is, have a successful salesman take him out and show him how to sell. Too often, however, after the good salesman had repeatedly demonstrated, the recruit would make a miserable failure when turned loose by himself. Now we send out trained instructors to do the teaching. They make demonstration sales, yes, but they explain beforehand just what they plan to do in the sales interview, explain why, and tell the beginner what to watch for. After the interview they break down the sale into its parts, asking the recruit questions to see whether he has "caught on," explain points he did not understand, call attention to bits of strategy used, objections avoided, etc., and answer his questions. The important thing here is that the instructor breaks down the total situation into its specific elements and shows the beginner exactly how each should be performed.

In the third step in job training—correcting mistakes made by the beginner—we must also admit that the importance of good methods has not been generally recognized. Perhaps we no longer bawl out workers as often as formerly, but to say that we have any generally recognized substitute technique would be going entirely too far. There are some excellent suggestions in Craig and Charters' "Personal Leadership in Industry" and in a few other published documents. As a general thing our literature of personnel management is full of statements telling what to do, but little, very little, telling *how*, particularly as regards the teaching on the job.

Technique of Training on the Job Largely Unrecorded; Much in Existence Not Recognized as Such. Some say that good teaching, in industry as in the schools, is an art and cannot be taught. We often hear about the "born

teacher." But we used also to hear about having to be a born salesman before one could sell. No modern sales executive now believes that ancient dogma, because such concerns as the National Cash Register Company, The Procter and Gamble Company, and many of our leading insurance companies, have abundantly proved it false. The basic reason for the absence of technique from our literature and from our discussions is not so much that little exists as that we do not recognize it when we see it. Those of us who teach or are concerned with teaching are so close to the work that we lose sight of the methods in our concern for results. Such excellent results have been achieved by many companies that we cannot give all the credit to excellent selection of persons to be trained. Much of our known technique remains unrecorded, also we are unconscious of much that actually exists. As Dr. Charters pointed out years ago, we must seek out the unrecorded specifics of successful teaching practice and get them down on paper for careful study.

Some Bits of Technique. In my search for information on the technique of training on the job I received two types of responses to my request for descriptions of how training on the job was being done. Some described their training plan or system, as though that was what technique amounted to; others plead "not guilty" to having standard methods of instruction but, in telling about training work, let slip a few bits of technique which, while varying from excellent to only fair, indicate that the hope of bringing this factor in training to the forefront of consciousness is not altogether vain. A few quotations will bring out my meaning more clearly.

Western Electric Company, relay winding department: The first thing the instructor does is to place the new operator at her ease, get her located as to locker and washroom, ringing the clock, showing her a good place to eat at noon, etc. One step at a time is undertaken in the instruction. First, the disposition of material on the bench; next, the folding of splice papers. They are kept three days on this, and an instructor takes care of a class of three. Then they are passed on to another instructor who trains them in splicing. At this work they are kept a slightly longer time, and an instructor takes care of six or eight. Then they are taught simple winding, and so on step by step until they are able to make the day work rate. Then they are moved along to another group in which an instructor takes care of twelve. Here they are coached until they can make the standard piece-work rate. From this point a slow operator is placed in a group of fast operators or alongside of a fast operator with whom she becomes more or less chummy and unconsciously develops the same rate of speed.

Note particularly how they have worked out the technique for developing speed. Perhaps it may not be the best possible method, but it is a recognized, standardized bit of technique. Just how some of the other elements are taught is not indicated, but the teaching order seems to have been carefully worked out.

From the same company, coil winding department, we get, in elaborate detail, the specifics of how to do the job safely. Each of thirty-two safety rules is taught at the point in the job instruction where its application is indicated by job analysis. Here are a few of the specifics:

1. Do not wear long loose sleeves (short sleeves to elbow are preferred).
2. Do not wear wrist watches, and do not wear rings on the little finger, as they very often come in contact with the machine switch and cause electric shocks and burns, also burning jewelry.
3. Be sure the handle of the tail stock is down after chucking spool, before starting to run the machine.
4. Use thumb and index finger to tighten tail stock; do not use the little finger and third finger, as the little finger is apt to get bruised.
5. Do not talk when you have the soldering iron in your hand.
6. Do not shake the soldering iron on the floor, as the hot solder splashes on your neighbor's feet, causing burns.
7. Do not try to pack your work while the machine is running.
8. Push your chair in when you leave your place.

Again from the same company comes this bit of technique, not of training on the job, but certainly contributing to it.

Our first efforts were concentrated upon improvement of the supervisory organizations . . . We have made extensive use of conferences of sub-foremen which are based essentially on Allen's "The Instructor, the Man, and the Job," with the aim of improving the ability of these first line supervisors to teach workmen reporting to them . . . This has resulted in bringing the job training proposition directly to the supervisors' attention in such a manner that they wanted to do something about it themselves and looked to us for aid . . . They have been given an understanding of the methods by which they may do this training.

With workmen we have practiced the principle of job rotation, aiming largely toward despecialization. This same principle has been followed in developing supervisors.

Supplementing these training activities we have a plan of classifying and grading field employees, using a numerical system of indexing experience. By this means supervisors are at a glance informed of the training the workman has had and what is required for his further development. The use of this plan of grading has promoted among the supervisors much interest in job training.

In the plant of the Tennessee Furniture Corporation there is an elaborate technique for keeping track of individual training needs, which serves to keep the shop superintendent and department foremen as interested as are the department instructors. I quote:

We have devised a method for keeping an inventory of the skill in each department. We make out a chart for each department, and for the first rating the shop superintendent, department foreman, and department instructor decide on the skill of each man and stick various colored pins accordingly. Then once a month the foreman and the instructor make any revisions that they think justifiable.

Also from this sheet is made up the training budget each month. For example, on the Mattison lathe set-up at one time it was found that we had only one man capable of doing this work. It was the plan of the instructor to take someone else who was a good knife grinder and work him at odd times on set-ups for this machine until he was capable of doing the job. Likewise, on all jobs that were not properly guarded, we outlined training to cover.

The color of the pins vertically on the chart shows how well the jobs are guarded, while the color of the pins horizontally denotes the skill of the various

operators. We found that both foremen and superintendent watched these charts very carefully.

Teaching Teachers How to Teach. At the Scovill Manufacturing Company, good training results have been achieved largely because of the emphasis which has been put on teaching methods. When the training director was a boy of seventeen, learning to be a machinist, he suffered under a foreman who assumed that telling was teaching. Whether as a result of that experience or not, he is now making sure that no apprentice under his charge fails for lack of correct instruction. He has analyzed exactly what he wants to teach each boy on each machine as well as in each trade. Then he has taken the men who must do the teaching and has taught them how to teach.

At the Newport News Shipbuilding and Dry Dock Company the problem of teaching instructors how to instruct is considered of equal importance with determining what should be taught. I quote from a talk by C. C. Via before a foreman's group in his organization.¹

Imparting new ideas to others is of itself an art by no means possessed by all. In our course on methods of teaching the instructors learned that many times a full, clear and direct explanation left the learner hopelessly in the dark, and that the usual brief and hasty explanations encountered in the shop were even worse. They also discovered that a careful demonstration of a manipulative process frequently went wide of the mark. Apparently trivial details often turned out to be the most important factors in instruction. They had brought home to them the fact that, when they stood in front of a person to show him a process, to that person every move was either reversed or upside down. They also discovered that the average person can assimilate only about eight new ideas at one bite—if more are to be taught the lesson must be divided to avoid mental indigestion.

In this school they learned the four steps necessary to put across a new idea, namely:

1. Preparation of the learner's mind.
2. Presentation of the idea.
3. Application of the new idea to the learner.
4. Testing the thoroughness of the learner's understanding of the new idea.

They were also coached in the different methods or tools used in carrying through each of these four steps.

Leffingwell, in his admirable discussion of "The Office Supervisor's Part in Training," outlines clearly the six important and necessary steps in teaching the job to an office clerk.²

Developing Technique in Department Store Training. From the department store field comes one of the best and most complete programs for training on the job, with some emphasis on technique. In Kaufman's department store, Pittsburgh, training is recognized as a primary function of every person in a supervisory position, and the ability to train is one of the major factors considered in judging the worth of an individual or his fitness for promotion—this by executive order from the president. No training job is allowed to

¹ Lecture 4, 1927-1928 series, *Foremen's Lectures*.

² See p. 809.

be so big that it takes the executive or supervisor away from other important duties, but it is considered just a part of his regular job.

The most significant principle sponsored by the store is this: Every training job should be done by the person best fitted to do it. That is, within a department, each position for which training must be given is divided into specific training tasks, which are assigned according to the training capacity of the various individuals within the department. For example, when a new girl comes into a sales department, a number of persons take her in charge in rotation. First there is a coach to introduce her to her job—make her feel at home, so to speak; then a stock location coach, followed by a merchandise information coach, a technique of selling coach, etc.

The technique of installation is as follows: First the president calls a conference with the merchandise manager and personnel manager, at which training needs of a department are discussed and, if necessary, the training program is sold to the merchandise manager. Then the merchandise manager calls a meeting of the particular department buyer, the personnel manager and the head of the training division. They sell the buyer and pick the man in the department who is to be in charge of training. The buyer then calls a meeting of the training division manager, the training supervisor who is to assist in the work, and the selected trainer. At this meeting they sell the program to the trainer, pick out a coach for each training job, and make plans for the training.

The training division now gets together the training material required and sets up the methods to be used in teaching it. When this is ready the training supervisor and the department trainer assign a particular training job to each coach, according to individual fitness. Finally, the supervisor teaches the department trainer how to train his coaches.

There are other important elements in the total training program, especially those which have to do with appraising conditions within a department before training begins, and the follow-up after training begins (1) to see that the training is carried on according to plan; (2) to correct any faults which appear; and (3) to appraise the results secured; but these are not pertinent to the subject of our particular interest.

We are probably indebted more to Dr. W. W. Charters than to any other one person for such specifics of training technique as have been recorded. In the insurance field many training men give him credit for directing their thinking to the problem of training technique. John A. Stevenson, who has been an outstanding leader in the training field, and whose book, "The Project Method of Teaching,"¹ has been of great help to those seeking light in this field, has often publicly acknowledged his debt to Dr. Charters.

It is natural, therefore, to turn to the fields where Dr. Charters has been at work in order to find the kind of material which can properly be called technique. In a recent publication, "Personnel Research in Department stores,"² there are numerous references to such material, mostly contained

¹ The Macmillan Company, New York, 1924.

² The Research Bureau for Retail Training, University of Pittsburgh.

in training manuals for member stores, and in a few cases some elements of the actual training methods are detailed.

As a part of its work in devising a technique for "teaching stock" to new sales clerks, The Research Bureau for Retail Training developed a stock card containing a set of questions, the answers to which, if properly learned, would enable the sales clerk to handle her job satisfactorily as far as knowledge of stock was concerned. This card was given to the instructor or coach, not to the clerk—at least not at first—and contained directions and suggestions for teaching the answers to the clerk. For each question there was a specific suggestion regarding the methods to be used in teaching the answer. For example:

Question 1. What are the main sections in your department? Where are they?

Suggestion to instructor. Show salesperson the sections as you name them.

Among the directions to the coach we find:

Tell the salesperson to go through the stock, answering the questions for herself (this at the end of the direct instruction).

Tell the salesperson you will ask her later to answer the questions when she has had time to study the stock.

The Research Bureau learned early, it seems, that directions for instruction could not be too detailed or specific. In a discussion on teaching salespeople how to do suggestive selling, we find:

It is necessary to define quite clearly what is meant by suggestive selling, and to point out its advantages and disadvantages . . . It is absolutely necessary for a salesperson to have some definite article in mind in order to suggest effectively.

It seems clear that the more concrete the training, the better. That is, it is necessary to show in definite ways how suggestive selling can be done, whether by selecting certain articles for the salespeople to suggest, by talking over the possibilities with them and getting them to make their own suggestions, by demonstration sales or plays, or by some other specific means.

Teaching an Office Supervisor How to Train Clerks. Dr. M. A. Bills discussing the problem of training section or division heads in managing their workers, tells a very interesting story:

Most of these men have grown very slowly into the supervisory jobs. They have often worked at every job in their section. Therefore they know quite thoroughly the work to be done. But no one has ever taught them how to direct the work of others, and they have not picked it up. They usually lack flexibility and when the supervisory work is put upon them they are likely to fail because they go about it in the same way they have handled their individual work. You all know section heads who are unable to delegate work properly and who wear themselves out trying to do it all themselves. It is the natural result of lack of training.

I want to tell a story which will illustrate to you that it is possible to train executives and that supervisory ability is not innate but may be acquired. About three years ago the supervisor of a group of about thirty clerks was given an assistant to help him in the work. It was one of the cases where one department passes a lemon to another. The man was a good enough individ-

ual worker but he was a "grouch." In fact, in any contest he would have taken the prize as the worst grouch in the company. At first the supervisor had very little hope of training him in the work of supervising the division and devoted most of his time to teaching him to do the personal work which fell to the lot of any person managing that division.

One day the man came to him with a self-rating scheme. He had rated himself on all of the qualities and asked the supervisor to rate him. The supervisor considered the matter seriously and decided that he would rate him honestly and rated him very low on all the qualities that demanded contact with people. The man was very much surprised at this. It had really never occurred to him but what he got along as well with his fellows as other people did. He supposed that everyone grouched when asked to do anything and did not consider it as especially due to his method of asking that the girls in his division seemed displeased. The supervisor talked the matter over with him and they decided to see if he could be trained to get along with other people.

The supervisor started in immediately having him do a part of the supervision. When a new girl came into the office, the supervisor told him to explain the work to her, *using just about such and such language*, then to go away and leave her and not go back for a certain period unless she manifested signs of distress. Then, if she had finished the assignment successfully he was to continue the instruction *along such and such lines, using about such and such language*. If she had made mistakes he was to correct them and to *say about so and so to her*. This definite training continued until one after another all the points of supervision in the division were covered. The supervisor told me afterwards the hardest thing that he had to *teach him was to smile* when he was giving instructions or making any criticism of work done.

Last year the supervisor was promoted and the assistant supervisor has handled the division successfully ever since. However, the most remarkable part of the story is that this training was specific and not general. The man is still a grouch outside of the office. A short time ago the woman to whom he was engaged broke her engagement because of his bad temper. He has been asked to resign from two clubs because he does not know how to get along with the members and he is at present not living at home because of trouble with his immediate family. But in the office the man supervises, and supervises successfully, a group of thirty clerks and the pleasantest of relations exist.

Technique in Training Field Salesmen. This field presents the greatest obstacles to standardized training technique, but also the most fascinating possibilities for technique suited to specific selling situations. A few bits of technique taken from interviews with successful trainers are given:

1. If a new man, in figuring the premium on a policy for a prospect, makes a mistake and quotes the wrong amount, I cut in with: "Just a minute, Bill, you meant to say \$32 instead of \$38, didn't you? I know it was just a slip of the tongue, but I want Mr. Prospect to get the right idea of the low cost, etc." After we get outside I call Bill's attention to the mistake and warn him to be careful; such mistakes may cost him business. I make a note of it and that evening I have Bill figure out a lot of premiums so he'll not make the same mistake again.

2. Teaching a new salesman to plan his day's work is one of the most important things in our training plan, and one of the easiest, as far as building a habit is concerned, but one of the hardest to get him to think through properly. We have some rules and guiding principles about planning which

he has read and studied before starting out. I have to teach him how to apply them.

On our second day of training I have him carry the dealer record book and tell me just before we enter each store, just what I have planned to accomplish, as shown by the symbols (which I have previously explained to him). That shows him how much importance I attach to planning and starts the habit of consulting the book and going into each store with a definite selling plan in mind. When the call is over, and we are out in the car again, I ask him to check up and see if I accomplished my objectives. That gets to be an absorbing game and sells him on the idea of definite plans.

That night, and for several succeeding nights, I give him exercises in planning. First I take a few sample dealer records and explain the significance of the various facts in the record of past sales and the personal data about the buyer. Then we plan the next day's calls together. That involves discussion of the rules for planning—how to take into consideration such factors as national and local advertising, special prices, "free deals," competitive activities, etc., all the time keeping in the forefront the territory quota for the various items he has to sell. As I take up each card I point out the important facts and ask him to suggest the proper objectives to be set for the call. If he makes good suggestions I accept them enthusiastically. If he misses the ball, so to speak, I make him think it through by asking questions until he sees the point and realizes why he was wrong.

On the second night of planning I give him the whole list of proposed calls and have him write out the plans on paper. Then we go through them one by one, and I raise all kinds of objections to see if he really understands why he made each plan. As soon as he is able to justify his plans by giving good reasons and quoting the rules, I figure he has had enough.

It takes time to teach planning, and some experience on the salesman's part, of course, for the rules do not cover everything and the facts about the local situation and the dealer's personal characteristics cannot all be put on the cards, but by going at it systematically this way the beginner soon learns to use good judgment in combining all the facts in determining upon his objectives and his sales methods for each of twenty or more separate calls every day. The game of checking up each day on how closely he was able to carry through his plans remains highly interesting, because it gives him a measure of his progress.

What We Still Need. Under the present conditions as regards training technique we are not in a position to attempt any formulation of principles or standards. What we need, and what I hope these examples have emphasized, are specific, detailed descriptions of just how effective training has been done on thousands of jobs under all sorts of conditions and circumstances. Combined with these data we need the records of hundreds of experiments in training methods built upon the principles and theories advanced by our leading educators.

We who are seeking to discover and perfect technique must always and forever keep asking the question: *Just exactly how* is it done, or to be done, as well as what, and when, and where? We must ask the expert teacher: Just what do you do in these specific situations? If he or she is unable to tell us—probably even if able—then we must have trained observers set down the methods wherever that is possible. Perhaps we must call upon the latest scientific recording devices, so that verbatim records and motion

pictures can provide the objective, uncolored facts of actual technique under natural, normal conditions. The presence of an observer often changes the training conditions seriously.

In the insurance field some companies are now securing stenographic records of the beginner's actual sales presentation through the courtesy of business friends who provide bona fide prospects and also a concealed stenographer. The purpose is to discover the salesman's weaknesses, and the stenographic record is actually gone over with him as a basis for mutual agreement as to the further training which he needs. On the other hand, we have some few companies which make reasonably sure of what the recruit will do and say under ordinary circumstances by forcing him to learn by heart the prescribed demonstration and sales talks, even to the fine points of voice pitch and inflection, arm and hand movements, and facial expressions. The training in these cases involves more of the old classroom practice recitation than of training on the job, yet the plan suggests some points which are equally important in field work.

Undoubtedly we are breaking away from the now largely discredited schoolroom methods, products of the past, which have almost completely dominated industrial training. But it is still supposed in many companies that training requires formal textbooks and manuals, classrooms and blackboards, lectures and examinations; that training is concerned with information—what to do, rather than how; that information can be imparted in logical order regardless of the need for it or its relation to the job in hand; that lectures and demonstrations on how to do the task should enable the student to do it; that the student who does not learn by these methods is lazy, indifferent, or mentally incompetent. We still hear occasionally of the sales executive who hires an outside go-getter to come in and train his salesmen by lecturing to them once a week on salesmanship and character analysis, while he himself goes out to play golf, patting himself on the back because he can now say that he gives his salesmen the best possible training.

If we must train, it is certainly the part of wisdom to do the job well. In recent years we have learned something about the objectives of training, the preparation of training material, the necessity for training on the job, and the responsibility of every executive for carrying on such training with his subordinates. We are even saying, quite boldly, that teaching is the primary function of every executive. When we get even an important minority of executives to admit that, we shall seem to have won a great victory. But it will be a hollow victory if our executives put on the form of godliness yet lack the power thereof. When their workers ask for the bread of training, they are likely to get stones. We must not slack our efforts in the training field until this acceptance of the responsibility for training is followed by acceptance of the fact that correct teaching methods are even more important. Our training program will be complete when, and only when, we have developed the technique of training on the job to the point where our training (1) fits the job; (2) reduces learning time to a minimum; (3) inspires the workers; (4) and develops the most effective work habits. It is such training that will pay real dividends to the employer and to the worker.

Summary. I have suggested, without intending to be hypercritical, that much of our present job training is ineffective and more costly than necessary because (1) beginners are expected to absorb good work habits through watching experienced workers; (2) industrial educators have not realized the importance of good teaching and have, therefore, left job instruction to those who have no great interest in teaching and who certainly have not been trained in the technique of instruction.

I have made this seeming indictment in the face of the facts that probably more attention has been given to method than appears to be the case, and that much teaching is probably done by men who have something of a natural flair for it.

Industry has failed to keep step with the progress in educational methods in our public schools, where problems to be solved take precedence over abstract principles, although industry has had a laboratory for experimentation which far surpasses that of the public schools.

Following this statement of present conditions generally, I described some advances toward effective training methods and pointed out that we need a great deal more experimental work along the same lines. I should like in closing to suggest a sort of platform or program as a basis of further effort to bring training technique into its rightful place in industrial and business training.

I shall assume that, as a preliminary matter, the particular job has been analyzed for its teaching content and that I know what must be taught in terms of the knowledge and skills required and the personal characteristics either necessary or desirable for success. My objectives are therefore clear. It seems to me that the first point in good technique is: Arrange the instructional matter and teaching plan to correspond with the order in which problems arise in doing the job because, of course, I would use the project method of teaching.

Second, from a study of the tasks to be done and the things to be learned in connection with each problem, I would arrange and teach them in the order of learning difficulty. I would know, and record on my training plan, the proper point or step in the teaching process at which each element of knowledge should be taught, because I would recognize that a fact is learned with least effort when the need for that fact has risen in the process of solving a problem.

Third, in teaching each element of manual or even lingual skill (for it applies in teaching selling), I would demonstrate under job conditions just how the thing should be done, and repeat the demonstration until the student was ready to try it for himself. I would judge his readiness by the questions which he had asked in response to my invitation, and by his answers to my questions. I would have the essential points of each step in mind and on paper so that guess work would be eliminated.

Fourth, I would let the beginner try, correct his mistakes one at a time by redemonstration and further explanation, and continue this process until the student had reduced the acts or series of acts to a habit.

Fifth, I would measure the individual student's learning ability as accurately as possible and endeavor to teach in each lesson only as much as the

student could grasp. I would teach slowly or rapidly, depending on the student, and I would make sure, by drill and examination, that each element was learned before passing to the next.

Sixth, I would maintain, at all costs, a personal interest in the beginner's progress and an attitude born of patience with and understanding of his human tendencies to make mistakes and to do as little work as possible.

Finally, I would keep an experimental, inquiring attitude toward my teaching methods, introducing new bits of technique suggested by others or by my own experience, and carefully recording the results secured. Thus I would contribute my share to the advancement of knowledge regarding the technique of training on the job.

THE FOREMAN'S PLACE IN A TRAINING PROGRAM

BY FRANK CUSHMAN, *Chief, Industrial Education Service, Federal Board for Vocational Education*

There are two fundamental problems involved in any plan of education or training for an industrial organization: (1) The problem of selecting and upgrading a selected group of members of the organization to fill higher and more advanced positions as vacancies occur, and (2) the problem of maintaining a reasonably high degree of efficiency in the entire personnel of the organization. The latter problem involves the securing of efficient production in the plant and also efficient handling of personnel factors which affect morale and efficiency on the job.

A Limited Number of Ambitious Employees. In any industrial organization there is always a limited number of individuals who are more ambitious than the average employee. In number these individuals will probably not exceed 10 per cent of the entire working force. Efficient operation of the plant, however, depends upon the best efforts of the entire personnel.

This small number of ambitious employees usually includes persons of superior ability and intelligence who are potentially capable of promotion. From the standpoint of conservation of human resources, such people should be encouraged to prepare themselves for promotion and advancement in proportion as there are opportunities for realizing their ambitions. In other words, they should be recognized to the greatest possible extent in connection with any policy for promotion from within the organization, since under such conditions this group is the reservoir on which the organization must draw. If an organization has no such policy the entire matter of promotional training becomes a liability rather than an asset for two reasons: (1) It creates dissatisfaction in the organization, and (2) it functions in training men, who, in order to secure promotion, must leave the organization which has trained them. In practically all situations, however, the great majority of the employees of any organization are of average intelligence and many have limited ambition for advancement. It is fortunate that this is true, because the number of jobs available on the higher levels is in turn limited. Most people who work have to be satisfied as well as possible and for long periods of years with doing ordinary work with relatively limited responsi-

bilities, and contrary to the theoretical idea, most of them are satisfied as far as the job is concerned.

The Relative Size of the Two Problems. From the standpoint of training, it is roughly estimated that not more than two to five per cent of the entire working force needs to be considered from the standpoint of definite training for promotion, under static organization conditions. These persons by reason of their intrinsic intelligence and their ambition are able to derive benefit from taking advanced instruction of a technical character which they may need when they are advanced to more responsible positions requiring a greater command of technical subjects and a better grasp of management problems. From this standpoint, it may be assumed that from two to five per cent of the entire personnel of the average industrial organization may pursue organized technical courses with promotional objectives in mind and thereby contribute to the efficiency of the organization by which they are employed. For the remaining 95 to 98 per cent of the working force the training problem, so far as the work of the plant is concerned, is, to a very great extent, one of handling incidental, unorganized or casual training on the job on a job upgrading basis. There are therefore two distinct problems which have little or nothing in common. The kind of training referred to for this 95 per cent of the working force is the kind of training which must be given in connection with the work of the plant in order to maintain a reasonable degree of efficiency in production. This training must be given whether the workers involved are ambitious or not.

Two Types of Individuals. Individuals who would be included in the two to five per cent of the working force are potentially equipped for positions as minor executives. Such individuals voluntarily attend evening school classes, buy books and study them at home during their spare time, or enroll in correspondence school courses without any pressure being applied by the persons to whom they are responsible in the plant.

The individuals who are included in the 95 to 98 per cent of the working force would include all of those persons who are more or less satisfied with ordinary jobs and who lack sufficient ambition to attend evening schools or avail themselves of other agencies which can assist in qualifying them for better jobs. The sort of education and training which must be carried on with this group is, as stated before, a necessary part of the work of some one in the plant and is carried on in some way in every plant whether the fact is recognized or not. The special content which is handled in connection with this incidental instruction on the job is intimately bound up with the knowledge and skill which foremen and experienced workers possess. In most cases this type of content is not found in textbooks. It is really a part of what has been termed the job intelligence of an experienced workman and is developed in any workman only through experience on the job under competent supervision.

Possession of Information Does Not Insure Ability in Performance. The possession of technical information in itself does not assure any ability to apply that information on the job in specific situations. Technical courses and in fact almost all organized courses of study or training can hope to do little more than place an individual in possession of information, except in cases where information can be practically applied and experience in using

the information can be secured. After this process has been completed the subject may be fairly said to have been learned. In certain lines of work, as, for example, related trade mathematics for machinists, new information can be applied by working out problems in advance of dealing with a practical job in the shop which calls for the same kind of a computation. Courses in industrial management, for men who are not even foremen, offer little in the way of opportunity to apply the information concerning management. Very often five, ten, or more years elapse subsequent to the completion of courses in industrial management before the men enrolled secure a promotion which enables them to apply the information secured.

General Characteristics of Technical Courses. The kind of technical information which is ordinarily included in organized technical courses deals for the most part with general principles. While the specific technical knowledge needed on a particular job involves some general principles, it is a very difficult matter in most cases for a man of limited education to apply general principles to a concrete situation. From the standpoint of good instruction it is far better to teach a man first to deal with specific situations and later on help him to see what the general principles are that characterize the different jobs which he has done. The specific and extremely concrete applications of technical knowledge which are needed on the job can best be handled by utilizing men as instructors who are themselves expert workers in the particular occupation in question.

What the Foreman Knows. The competent foreman possesses a great deal of special skill and information which he uses in dealing with specific situations. This special information is not necessarily in the possession of the higher plant executives and engineers. From the practical operating standpoint, he knows just about what his equipment will do, to what extent it can be crowded with safety, and what sort of troubles are likely to develop if it is not handled in particular ways with proper safeguards. An illustration of what is meant here is found in an individual who has owned an automobile and driven it himself for four or five years. He knows just about what his car will do under different conditions of weather and on different types of roads. Unconsciously, he knows exactly how to handle that car in difficult situations. In fact he knows more about that car than he knows about any other automobile in existence. Provided he is a skilful driver, he can handle his own car which he has been driving for a period of years with a greater degree of skill than he can handle any other car. He can, moreover, handle it with a greater degree of skill than any other person can handle that particular car. The situation with respect to every piece of equipment in a shop is somewhat analogous to that of the automobile. A man who is intimately acquainted with a machine tool, a hydraulic press, a steam boiler, or other apparatus or equipment, has a practical knowledge of how it may be expected to perform and how it should be operated which is different from that which any other person has. Where a man is thoroughly acquainted with a machine tool or other mechanical device he acquires an ability to anticipate troubles before they develop, and when anything goes wrong, he can locate the trouble quickly and knows what to do to correct the difficulty. This sort of knowledge of equipment—what it will and will not do under given conditions—is a

part of the job intelligence which a foreman has and which a superintendent cannot be expected to have concerning all departments of a plant. Moreover, this sort of practical knowledge on the job is, to a very great extent, what keeps a plant running smoothly and efficiently. In proportion as the foremen are thus competent and expert in handling their equipment, the entire plant will be free from trouble, breakdowns and accidents.

How Job Intelligence Is Secured. A foreman does not possess job intelligence by virtue of the fact that he is a foreman. He possesses job intelligence only when he has come up through the organization and has passed through working experiences on the job which have brought him into intimate contact with the work and with the equipment. It is a significant fact that the best foremen do grow up in the organization in just this way. From time to time many attempts have been made to prepare young men for foremanship and other executive positions so that they could enter upon their duties as foremen or superintendents immediately upon completion of a preparatory course of training. It is a well-recognized fact that all such attempts have for the most part failed, and the fact remains that foremen are selected from the working force. Whether the fact is recognized or not, they are selected because of their job intelligence, in addition to their other qualities such as ability to handle men and work in harmony with the organization.

How Can the Foreman's Job Intelligence Be Utilized? The question naturally arises, How can the foreman be utilized in connection with the training problems which exist in every industrial organization. This question will be discussed from two standpoints: (1) With respect to the selection and handling of the 5 per cent who are in line for upgrading and (2) with respect to the training of the 95 per cent for efficient performance on the job.

What the Foreman Can Do for the 5 Per Cent. It does not seem to be possible to utilize foremen directly in handling the instruction and training of the 5 per cent of upgraders. Such education and training for promotion is, after all, a matter which lies outside of the average industrial organization. If it does not lie outside of the organization in all cases, there are probably more cases where it lies outside the organization than inside of it. In perhaps the majority of cases, ambitious and progressive men who are desirous of equipping themselves for promotion avail themselves of educational opportunities of their own initiative. The number of plants, however, is constantly increasing where definite attention is given to work in this field. For example, in one large organization the established policy is to reimburse employees for all expenses incurred by following through any course of instruction in any subject. In addition to the reimbursement, the company furnishes advice to the men with respect to their educational work, and in a number of ways endeavors to encourage ambitious employees.

The foreman may, however, be utilized as an instructor provided there is an evening or part-time school organization where he can function as an instructor with men from the plant where he is employed. Another very important function which he can perform with the 5 per cent is to help in the selection of men potentially qualified for upgrading and advancement in the organization. It is entirely reasonable to assume that the foreman, because of the close association with men in his department is

likely to size up his men from the standpoint of the characteristics heretofore discussed of the 5 per cent. In addition to helping in the selection of these men and perhaps assisting in some way as an instructor for them, he is in a position to encourage them to go ahead with their work and pursue their studies to the point where they will be nearer to realizing their ambitions. Conversely, the foreman can exert a very great influence in discouraging men from making any effort to better their condition, and can, if he cares to do so, neutralize, to a great extent, all of the efforts that others in the organization may make to encourage them.

What the Foreman Can Do for the 95 Per Cent. So far as incidental training on the job for the promotion of operating efficiency is concerned, it is safe to say that the foreman always has this job to do under average conditions. He may, of course, utilize assistant foremen or some experienced workmen to carry part of the load, but, in the last analysis, it is the foreman's responsibility to take care of the unorganized, fragmentary, and somewhat disconnected instruction on the job which is necessary to get the job done and maintain production. Such being the case, the question naturally resolves itself into a consideration of what can be done to enable the foreman to take care of this instructional job more efficiently. As is the case with almost every other kind of a job, the actual value of the job which the foreman will do in taking care of his instructional responsibilities will depend upon his attitude toward his job and toward the company. In order for the best results to be secured, there must be a *real* rather than an *assumed* interest in the work and the foreman must do a good job because he *wants* to rather than because he *has* to. In other words, a good job in this field by the foreman means the most genuine kind of cooperation with the management. There is a great deal of evidence to support the statement that this sort of cooperation cannot be secured by orders or by the direct exercise of authority. It can be secured only when the proper appeal is made to the foreman's pride in his work and through the utilization of such well-known interest factors as job pride, confidence in the management, and the proper placing of responsibility. The kind of instruction referred to in the preceding paragraph, the competent foreman recognizes as a part of his responsibility. He is potentially interested in doing a good job in his own field of work. The principal difficulty is that he is, as a rule, more or less inarticulate with respect to the whole matter. The question, therefore, is largely one of assisting the foreman so that he can do a better job in this field and of building up his confidence in his ability to do a good job. In the case of foremen who have never thought very seriously about what their responsibilities are, because of never having had their responsibilities analyzed and discussed by someone competent to do so, it is a relatively easy matter to secure their interest and cooperation if the right methods are used. Experience has indicated that where foremen are given a little insight into the methods of instruction used by experienced and successful teachers they are usually very appreciative of this help and anxious to apply good instructional methods for the purpose of doing a better job in the plant.

The Foremen's Conference. One of the most practical methods that has thus far been discovered for accomplishing some of the preceding objectives

is the foremen's conference, and this may well be considered as a desirable first step in the development of any program of education and training in an industrial organization, provided the plant management is interested and has the proper appreciation of the functions of foremen's conferences. It is, of course, utterly useless to carry on any program of foremen's conferences in a plant where the higher officials of the company are unsympathetic, or antagonistic toward the idea. The foremen's conference has been very extensively utilized in all sections of the country, and, in a very great majority of cases, the results secured have been of far greater importance and significance than were anticipated in the beginning. In many plants where foremen's conferences have been held and no follow-up program was organized the program has stopped temporarily because there was some uncertainty as to what the next step should be.

Suggestions for a Follow-up Program. There are several desirable types of activities which can be organized as a follow-up for a series of foremen's conferences in order to keep interest in education and training alive and capitalize to the greatest extent possible the results of a series of foremen's conferences. Among these activities the foremen's club is meeting with considerable favor. Competent leadership is, however, indispensable if a foremen's club is to function in any important way. Without leadership of the right sort a foremen's club may produce negative as well as positive results. A continuing program of foremen's conferences is an alternative plan. The success of such a program is, however, dependent upon having a leader who is resourceful and not likely to run out of ideas after a short period of time. There is a great deal of practical, as well as potential value, in the right kind of instructor training courses for foremen. The kind of assistance that such work may be expected to render to the foreman is a logical step in enabling him to assume and properly discharge the responsibilities for training which are logically a part of his job.

Problems of the Management. One of the problems which the higher executives of an industrial organization should recognize and solve has to do in the first place with creating a desire on the part of foremen and other minor executives to enter into a program of foremen's conferences and instructor training courses, and secondly, with making the conditions such that it will be possible for them to do this under competent leadership.

Another problem of the management is to see that those persons in the organization who are potentially capable of qualifying for advancement in the organization are provided with an adequate opportunity for securing suitable opportunities for education and training. For this group, which, as stated before, will probably not average more than 5 per cent of the entire working personnel, the company can well afford to set up the best possible plan of selection, using the practical knowledge and judgment of the foremen as a check upon the system used, no matter how scientific it may appear to be. After the persons have been selected, the company can well afford to encourage them to take advantage of opportunities offered through evening classes in public schools, correspondence courses, university extension courses, or special technical courses, organized and operated within the plant itself.

A Mainspring Is Needed. The best watch movement ever manufactured is of no value, as a time piece, without a mainspring. An educational program in an industrial plant needs a mainspring. A program developed along the lines indicated in this paper can best be developed by an individual who has enough tact and judgment to develop it in such a way that the demand for each new activity appears to come from the men themselves. Some of the most outstanding successes have been achieved by men who have developed their programs by getting the persons directly concerned around to the point where they wanted to do the thing themselves. This is of course merely an illustration of good management which successful persons responsible for the work of others utilize consciously or unconsciously.

Some Common Mistakes. A great deal of time, money, and effort has been expended in setting up general educational programs or providing educational opportunities for workers in industry merely upon the assumption that education in the abstract was a good thing for everybody. There are undoubtedly some values as far as morale is concerned which are derived from general programs. It is somewhat difficult, however, to discover in what way a series of lectures on Shakespeare's plays has any direct bearing upon the work of a marine engine and boiler shop. Some of the employees may feel that the company is very generous and considerate in bringing a professor of English to the plant for these lectures, but there is always a small percentage in any group which, under such conditions, will grumble about the whole matter and ask why, if the company wants to do something for the men, they do not distribute the money in the pay envelopes which they pay to outside lecturers. It makes not the slightest difference whether such general educational activities are organized in a plant or not, so far as the foremen's immediate instructional responsibilities are concerned. Even in extreme situations, where working time is spent in educational and recreational activities, the foreman's responsibilities for instruction on the job are not modified in the slightest degree. Such being the case, it cannot be claimed that miscellaneous inspirational or general education activities can have any particular bearing upon the incidental education and training which is going to be given anyhow on the job by the foremen to practically all members of the working force in the plant.

Coordinating Technical Training with Opportunity. So far as technical courses are concerned, the mistake is often made of providing an opportunity and then making the opportunity available to all persons in the organization regardless of their ability to derive profit or benefit from the work. When large groups of persons spend time and effort in preparing themselves for some other job, which for most of them is entirely out of their reach, the practical result is that a lot of them are made dissatisfied and unhappy.

This indicates that the sensible thing to do is to have some system of selection for those who are to be encouraged to secure advanced technical instruction or training as a part of a plant's training program. An illustration of the results of training large numbers of people for jobs that are out of their reach is found in the case of a certain company which employed a limited number of foremen. A private educational agency organized a foremen training course in the vicinity of the plant and by some means or other

secured most of the competent workmen from that company as students in the course. The principal purpose of the course was to qualify men to become foremen or superintendents. After completion of the work many of these men left the employ of the company where they had good jobs and good working conditions merely because they had become obsessed with the idea that it would be foolish for them to continue working for that company unless they could secure an immediate promotion. The net result in this case was negative. The values to the industrial organization, as well as to the individual men employed by it, were deleterious rather than constructive. In other words, the company and the men employed by it would have been better off without this so-called educational program which did little more than make a group of men dissatisfied with their jobs and helped to disrupt the organization.

Confusion of Objectives. There is evidence that considerable confusion prevails in mapping out programs of education and training for persons employed in industry. This confusion, to a very large degree, results from a failure to analyze existing situations and determine what it is that needs to be done. The practice is all too common of seizing upon an idea and developing it without any particular regard for the results which may be expected to come from the development.

In handling problems of education and training in industry, procedures are followed which would not even be considered in handling matters concerning production and sales. The procedure which appears to be most nearly correct and scientific is first to analyze the needs and determine what it is that needs to be done; second, to devise ways and means of accomplishing the objectives as determined; and third, to set up conditions which will make it possible to accomplish these objectives. In carrying out this procedure the management has definite problems and responsibilities. In solving these problems the foreman can make a contribution which no other group within the organization can make. One outstanding problem of the management, therefore, is to train and equip its foremen to discharge the responsibilities, in the field of training, which are an integral part of their jobs, in the best and most efficient manner possible.

TRAINING PROMOTION PROSPECTS

By BYRON F. FIELD, *Superintendent, Training Division, Commonwealth Edison Company*

It is axiomatic that every employee, if properly selected, has promotional potentialities. Most employees assume this as do some managers. However, training all of those in a given grade to proficiency sufficient for them to fit into the next higher grade is not generally practiced, and where practiced, is usually confined to the lower ranks.

Definite job-training material, secured by job and difficulty analyses, and a program for its presentation to employees has been developed in many industries. This program may be carried on on the job with the employees'

supervisors acting as coaches or instructors, in a special location with special coaches, with or without written material for the permanent use of the employee. In most cases, however, regardless of the method used, the practice is first to train the employee thoroughly in the position which he is occupying, and to follow this by training, in part at least, in the functions he would perform in the next higher grade.

The procedure of surveying the field within a company in order to select a limited number of promotion prospects for executive and subexecutive positions early enough to permit special training in advance has not been widespread. Often management has waited until the incumbent died, resigned, or was retired, and then looked around for "some likely fellow to take Bill's place." This has resulted in so many disappointments that an increasing number of industries have adopted one or more of a variety of methods to assure having trained men to step into the more responsible positions.

The Understudy Method. Probably the oldest, as well as the most widespread, method for training men for higher executive positions is the so-called understudy method. While usually not conducted formally, and while as often as not carried on as a matter of convenience, the plan does give considerable training. Every executive, consciously or unconsciously, feels that he has one or more subordinates who should be promoted to his position when he leaves it. The executive then formally or informally gives this prospect understudy training in order to acquaint him with the duties and responsibilities of the higher position. Under this plan, the prospect, who frequently is the assistant of the one holding the position in question, is admitted into executive conferences, reads reports addressed to or sent out by the executive, and even takes his place in case of his absence, with or without limitations as to the extent of his authority and responsibility during that time.

Training of this sort is the personal responsibility of the one being understudied. Since this is true, the thoroughness of the training given, the breadth of view presented, and the points emphasized are a direct reflection of the attitude and interest of the person doing the training. Generally speaking, he will stress the things in which his greatest personal interest lies, and minimize the others. Thus, actually, he is creating an understudy with points of strength and weakness similar to his own—and with relatively little broadening experience.

Executive Information Files and Interviews. Going to the opposite extreme, a growing number of companies are taking a broad company view of the executive training and promotional field. Some companies attempt to maintain a file in which the education, training, and experience of each of its executives and potential executives is listed. An effort is made to keep this file up to date so that on short notice, when a vacancy occurs or when one is anticipated, the person with the necessary qualifications to take the position may be readily determined.

In a few organizations, a responsible executive, in whose office the file is kept, maintains an interview schedule. He regularly calls in each of the men whose records he has for a discussion of his activities, interests, prospects, and

ambitions. He records his reactions to each man interviewed, and these are also considered when promotions are contemplated.

Specific Executive Promotional Training Courses. A newer device which is coming into constantly increasing use, is the executive training course set up to provide a routine procedure for the training of promotional prospects. Industries conducting such courses select prospects from membership in them, with or without a definite position in mind for each prospect at the termination of the training period. Men selected for training may simply be considered good promotional material.

In some such courses, the men selected may be rotated between various departments at intervals sufficiently separated to allow them to become reasonably well acquainted with the functions of, and methods followed in, these departments. Some companies provide that those taking the course shall be given responsible positions carrying definite authority in each department visited. Others provide that the prospect shall be given a staff position to handle special assignments for which he can readily be fitted.

In some organizations this course is supplemented by, or supplements, classroom work in such courses of instruction, technical or otherwise, as may fit the employe to assume a promotional position. Some such courses are followed by formal examinations.

It can be seen that the basic aim of such courses is to increase the fund of general information regarding the company's financial and operating methods, as well as its policies, rather than to impart a mass of information regarding a single department. This seems to be based on the idea that what is desired in an executive is a broad understanding view of company and interdepartmental problems and policies. With this, provided the prospect has keenness of mind, it is assumed that he can rather speedily adapt himself to the new position.

Since the training is not directed toward a specific position, various practices as to the degree of assurance or inference that the promotion will follow the training period are used. Generally speaking, the companies inducting the smallest number of men relatively into the course and giving them the greatest degree of authority during the course, most often make selection for membership tantamount to an assurance of promotion. The inference is usually felt that promotion will follow completion of the course even when the assurance is not given or is denied. This so frequently results in maladjustments if the promotion is not forthcoming, that many concerns will not use the method at all.

Background Executive Training Courses. While the companies using the method just described ordinarily induct a relatively small number of men into the course, other industries use more general stimulating devices in order so to upgrade the majority of their minor executives that many of them, with a little additional specific training, may theoretically be fitted into a higher position in the department which employs them. It is felt that by this means the entire subexecutive group is improved by receiving useful information and by a better understanding of the company, and its problems. Where such courses are given, there is no inference that immediate promotion will follow completion.

Cooperative Educational Activity. Many companies encourage their employees, financially or otherwise, to take additional educational work either in company or publicly maintained institutions. Here, the aim is to broaden the employee's knowledge either of business fundamentals or of the specific field in which he works.

Present Trend. The answers to a recent nation-wide questionnaire indicated that more industries are interested in the methods of training their higher executives than in any other class of training. Apparently the training of the men in the lower ranks is felt to be well established and has proven to be so worthwhile that similar or greater benefits are assumed to follow from a more conscious training of the men in the higher grades.

DECENTRALIZED EMPLOYEE TRAINING¹

BY W. J. DONALD, *Managing Director, American Management Association*

The training of employees in business is as old as the relationship of master and servant, but methods have been changing with the changes in industrial and commercial organization, and of recent years have been affected substantially by modern principles of educational psychology.

The training of manual workers has thus far received much more attention than that of those often referred to as "white-collar workers," such as retail sales people, office workers, and persons who sell to retail stores, to the consuming public in their homes and offices, or to institutions or other manufacturing companies.

Comparatively speaking by far the greater percentage of those gainfully employed in America have heretofore been engaged in manual occupations, but the distribution of workers is rapidly changing because the increase in the size of business is increasing the number of office operations more than in an arithmetical ratio, and the keenness of competition has brought about a rapid increase in the number of sales people. Consequently the attention which heretofore was devoted solely to the training of manual workers is now gradually being shared equally or even to a greater extent with the training of commercial employees.

It is only natural that the training of manual workers has acquired a certain stability which is attended by distinct disadvantages, particularly a comparatively marked lack of progress.

Training of Commercial Employees Comparatively New. The training of commercial employees, that is, office workers and sales people, is comparatively new, and while it suffers somewhat from the traditions that have been borrowed from the field of training manual workers, nevertheless in many quarters the training of commercial employees is being attacked from a new angle by men scientifically trained in educational psychology and methods, and there is distinct evidence that the recent progress in such training is having a definite effect on the training of manual workers—so much so that educational directors in charge of training manual workers are

¹ Reprinted by permission from *Mechanical Engineering* for November, 1930.

reevaluating their objectives and methods and adapting to their situations the methods which are being applied in the training of sales people and office workers.

As a management policy, the training of workers is becoming more and more important. In the first place, the stoppage of immigration by the World War and its restriction since have limited not only the supply of manual workers but also that of office employees and sales people. No longer can an ample supply of unskilled workers be secured from the steady influx of immigrants. Wages have rapidly increased. A rapidly increasing percentage of foreign born speak English, this percentage being influenced by the fact that the annual influx of non-English-speaking persons is relatively much less important in relation to the total of English-speaking than before the war.

High wages for manual work in factories made manual work for females more attractive, and women workers who might otherwise have entered commercial occupations were attracted to factory work, leaving a dearth of them for offices and sales positions as compared with what might have been the case had the earnings of manual workers not increased.

Another new factor in the realm of office and sales positions in particular has been the trend toward the measurement of office and sales output, with a consequent increase in output per day per worker, out of which can be paid a higher scale of earnings. As yet, however, comparatively few office workers are paid on a piece-work basis or its equivalent. A somewhat larger percentage of sales people, either in department stores or elsewhere, are paid on a commission or partially on a contingent basis.

If a high wage policy is accepted, either as a matter of sound business or of necessity, it becomes imperative that under a daily-wage or straight-salary plan attention must be given to training if the unit cost of output and of doing business is to be kept down to a point which is essential in an era of keen competition. Consequently employees, whether they work on a salary or on a contingent basis of compensation, must be trained by their supervisors in order that their output may be commensurate with the compensation they receive.

The payment of employees, especially retail sales people or other sales employees, on piece rate or on a commission or other basis of compensation contingent on results is usually attended by a comparatively high turnover, and it is well recognized that excessive turnover of employees is expensive, not only because of the cost of employing, but also because of the high cost of initial training and introduction to the job, and especially the training that is necessary during the first few months of work when a new employee is probably not fully earning his or her compensation, at least in proportion to others.

This turnover among commercial employees is more costly than formerly because of the comparatively high earnings of the present decade, and it is especially high in those occupations where earnings are contingent upon output, because an employee who cannot quickly learn to earn close to the average is very likely to become discouraged and resign.

While there are other factors in the reduction of turnover of employees such as proper selection, good working conditions, etc., nevertheless it is

recognized that one of the most important of them is adequate, well directed, and effective training.

Another phase of the situation is that a number of modern educationalists have either entered the business world as business executives or have had such close contact with the business world that it has been possible to develop methods of training more in line with modern pedagogical practice and more fitted to the training of employees in scattered groups, including workers in comparatively small offices, salesmen in the field, sales people in small stores, or manual workers in small factory units. This modern viewpoint can be summed up briefly as training on the job by the supervisor, combined with a program of training supervisors in the process of training their workers.

Origin of Training. Historically, training dates back to the earliest appearance of the master craftsman, the journeyman, and the apprentice, the apprentice usually living in the home of the master craftsman, learning the trade from him.

With the introduction of the factory system, the personal relationship between the master craftsman and beginner changed greatly. Whereas the master craftsman had formerly been owner, manager, workman, and, to some extent, tradesman, these several functions were gradually separated, and comparatively large-scale operations introduced several levels and types of responsibility and activity which gradually widened the gap between the owner and the beginning worker.

During the period of small organizations the training function became the job of the supervisor, usually referred to as a foreman or department head. To set up any formal training program would have been too expensive, and in other ways it would have been impracticable. The training of the new employee necessarily became the function of the immediate supervisor, who regarded it as a natural part of his duties. The average foreman or department head corresponded to a considerable extent to the master craftsman of the previous age.

Meanwhile, however, a differentiation unconsciously grew up between education and training. Whereas in the earlier handicraft stages education in the sense of training for general life relationships was largely a function of the master craftsman, gradually this part of education and training was absorbed by public educational authorities, especially in America, and the master craftsman was to a still greater extent than formerly relieved of that responsibility. Thus the supervisor's function was finally confined to a much greater degree to that of training for the job on the job.

Advent of Corporation Schools. With the coming of large-scale operations, training for the job became a much greater necessity, and industry and commerce began to give it substantially more intensive and formal attention. As early as the 1890's in America a few corporations had formed what were commonly called "corporation schools," the assumption being that the training function, formerly exercised by the supervisor, department head, or foreman, should be exercised by a department especially equipped and trained to perform the job of training the employees.

This change was due to the assumption that the department head or foreman could not be expected to train those employees who were responsible

to him, because he was too poorly equipped to teach, partly because it was assumed that he could not be trained to teach, and partly because it was assumed that he had too many other responsibilities, particularly those which grow out of a comparatively greater necessity for reports and for other "paper" work in a system of large-scale business.

Consequently, it was not infrequent for corporations to establish schools or educational departments, appointing as the head of that department some one who presumably was better able to train employees than the supervisor. Not infrequently a public-school teacher or official was chosen for such a position, particularly on the basis of a more complete education, and often particularly on the basis of personality. Quite often these directors knew very little about educational psychology. As a matter of fact, that science was still in comparatively primitive stages at the beginning of the corporation-school movement.

By 1913 there were in America a sufficient number of corporation schools to warrant the formation of a National Association of Corporation Schools, and this organization grew substantially in influence and numbers from 1913 to 1921. Meanwhile similar associations were formed in England, in France, in Japan, and in certain other countries.

Some of these schools adopted the pedagogical methods which had been in vogue in the public schools and in colleges during the time when the director of education had attended them. Without any particular knowledge of educational methods, he naturally adopted those with which he was most familiar, including often the formalism of the classroom and its more or less inevitable removal from occupational activity and other economic relationships.

This movement embraced a goodly proportion of companies which were interested in the training of commercial employees, that is, stenographers, typists, and dictating-machine operators, bookkeepers, clerks, retail-store sales people, and salesmen who traveled to sell to department stores or other retail companies, as well as companies interested in training manual workers, especially apprentices. There was even considerable attention given to training for export work.

Banks, insurance companies, publishing houses, department stores, security houses, and even manufacturing companies, paid attention to the training of commercial employees. They were influenced very largely by the practice of manufacturing companies in the training of apprentices and other manual workers, not recognizing that manual workers in factories are usually concentrated in large numbers in one location, whereas office employees are usually comparatively small in number, and sales people often work individually out of branch offices under comparatively intermittent supervision.

The war and the dearth of workers for offices and sales jobs emphasized the need for training, and employers grasped at every straw to solve their problems.

Unaccustomed to thinking about training problems as a part of their own jobs, the average executives naturally wished to delegate the new activity to others, believing that in this way they had absolved themselves from all

responsibility for training. Often, in addition, this motive was supported by a certain moral satisfaction over providing for the training of employees.

Business executives have no monopoly on visual-mindedness. But, if they can see desks, classrooms, blackboards, and a classroom full of students, to most of them it seems perfectly apparent that an effective job of training is being done. If to this physical evidence of training can be added graduating classes, certificates of graduation, records of attendance at classes and similar devices, they are easily persuaded that a remarkable training job is being done.

Whether output is being increased by such methods as effectively as it might be by other methods is a little difficult to grasp.

To sum up, it was only natural that in the first stages of training for employees, emphasis should be laid on those conspicuous evidences of training which superficially would seem to indicate their value.

By 1919 it had become apparent in America that many corporations were training employees without the formality of a corporation school, and this trend of thought found its expression in the renaming of the association "*National Association of Corporation Training*." These informal training programs appeared more particularly in offices and among sales forces—in other words, among commercial employees.

A few companies, particularly one large publishing house, had already developed an extensive program of training which made no use whatever of the corporation-school idea with its classes, formal instructors, examinations, etc., and this corporation had made a notable success of its training program.

Meanwhile there had come into business or into close relation with it a group of men who were leaders in the field of educational psychology and method, most of them thinking in terms of the project method of teaching.

Trend toward the Project Method of Teaching. For teaching purposes a project may be defined as a problematic act carried to completion in a natural setting. Applied to business, this means that training should be carried on under natural conditions of responsibility, supervision, and incentive, and under normal working conditions.

In recent years there has been a strong tendency for corporations to abandon the formal classroom-instruction method of training and to return to the earlier method of making training fundamentally the responsibility of the department head or supervisor.

There is, however, this very important difference that is being recognized, namely, that the supervisor should be trained in the teaching process, and that he can be trained to teach. We have abandoned the attitude that a teacher is born and not made, and we are rapidly abandoning the attitude that a supervisor, such as a foreman or office-department head, cannot be taught better methods of training.

Furthermore, we now recognize that the instructional material for training purposes, usually referred to as "instructional outlines," must be organized in such a way that the supervisor will cover all aspects of the training program so that they will not be left to mere chance or individual whim.

During this change in methods of training employees, public educational authorities were giving more and more attention to the preparation of youth

for industrial and commercial pursuits. The industrial and trade school supported as part of the public educational system became quite general.

The first tendency in this movement was to assume that the public schools could take a very large part of the program for training for business as well as education for life relationships, and for a time it was easy to find vigorous advocates of public educational institutions which would entirely relieve business of the problem of training for the job.

Business Cannot Transfer Training Problem Entirely to Public Schools.

In recent years there has been a distinct swing away from the assumption that the public schools could entirely relieve business of its own responsibility. It is now realized that the public schools have failed to perform the whole task of education and training for occupational activity, that the failure was inevitable, that the problem cannot be transferred in its entirety to the public schools, and that business, whether it wishes to or not, must assume its own share of the responsibility for training.

An increasing number of public educational leaders have accepted this principle, at first with regret, and more recently with some degree of enthusiasm.

At first, many corporation schools undertook what is generally conceded to be the responsibility of the public schools, namely, that of educating young people and even others for the broader relationships of life, most of which, of course, have some bearing on the effectiveness of an employee in his occupation. In a few cases this tendency was inspired by a successful chief executive of a company who had had few educational advantages himself and who wished his employees to have greater advantages than he had enjoyed. Paradoxically, his lack of these advantages had not conspicuously affected his own business success. For the most part this tendency has been and is being abandoned.

Organized business now expects the public schools to prepare youth for most life relationships, and by eliminating this feature from its own program, business can devote itself more intensively and effectively to training for the job.

In many quarters the terms "education" and "training" are used interchangeably; in others a distinction is made. For instance, by some education is interpreted as referring to the general training for life relationships, and training as a preparation for an occupational pursuit.

Dr. James H. Greene in his book, "Organized Training for Business," page 1, states that the term training should be restricted in its use to the organized learning-process situations where the acquisition of skill in technical processes or success in meeting definite commercial or industrial problems is the goal. To him training is a part of education, and for purposes of further discussion his definition may be accepted as fundamentally sound.

Time was when it was believed that training should be directed to the benefit of those who were comparatively new in business or in a particular activity. The emphasis on training for younger workers was particularly due to the conviction that older employees gradually lose, and ultimately lose altogether, the capacity for learning. Such a point of view also took it for granted that older workers could not be trained for new jobs or for transfer to other activities, or, for that matter, even for promotion. Another assump-

tion was also implied, namely, that older workers, especially executives, had already learned all there was to learn. Another background of these points of view was an assumption that the learning process had to do with the acquisition of knowledge of facts, and it was not clearly evident that the learning process is not complete until the learner's skill has been improved or, psychologically speaking, until there has been a change in his habits of action.

Management Largely a Training Job. Today there is a very different point of view. The president of one of our most progressive companies has frequently said that management is in large measure, eighty to ninety per cent, a training job. He illustrates by saying that on one occasion a number of executives of his company analyzed exactly what management is in terms of specific operations, and that after classifying all of the typical operations, nine out of ten of them were listed under education and training.

Along with other executives, of whom there are many, he regards the training of his immediate associates as a major part of his executive responsibilities, and assumes that the training responsibility goes on down through the organization from one supervisor to the next, and finally to the last or lowest rank of employees.

These major executives even assume that their own training is not yet complete, that business experience itself is a continual process of training, and that, furthermore, they may profitably share experiences with others in conferences and conventions, by reading, and by consultation, for the purpose of developing their own capacities in the rapidly changing business world.

It is well recognized, for instance, that the spread of large-scale business has brought with it problems of coordination and decentralization of executive responsibilities with which very few business executives are fully prepared to cope, because the methods of operating large-scale organizations require not only the necessary machinery and organization set-up, but also the grasp of a spirit and technique of development of executives without which the mere machinery of large-scale operation will be cumbersome and subject to a vast amount of friction.

If this sweeping pervasiveness of the need for training is accepted, the question, Who should do the training? becomes comparatively simple. There is only one possible answer, namely, that every supervisor must train. This conclusion must be perfectly evident simply as a matter of practical expediency. Office employees of a large corporation are frequently spread in small groups through many offices, either in the same building or even in separate buildings and even separate cities. Salesmen travel from city to city or from section to section of one city. Retail sales people for the most part must spend their time in their departments, meeting and serving their customers.

Furthermore, the great majority of employees who have suffered under the formalism of school and college have a conviction that school days are or should be over. Training for adults must as a rule, if it is to be favorably received, avoid those features which remind one of his status during youth. This principle is valid even to the extent that some companies have avoided

the use of the term training and have substituted some term such as "development," and many of them have used conferences as a means of developing employees, meetings in which there is as little as possible of the flavor of a formal classroom.

Training of Employees by Supervisors Sound Pedagogically. Pedagogically, too, the training of the employee by the supervisor is being accepted as essentially sound. The great weakness of much public-school education, especially in the past, is that the student experiences no activity by reason of which his habits of action may be changed or new ones formed. In much school work the learning process is still a passive one. We are all well aware, however, of recent developments in the educational world which have linked the learning process with activity, and, in the industrial and trade educational world, to some extent with occupational activity, at least in miniature.

In business the restrictions and handicaps with which the public educational leader is faced practically disappear. Public-school leaders in educational thought would give their eyeteeth for the educational opportunities which lie at the hand of every business executive and every supervisor.

In business the student-employee, whether old or young, a new employee or a veteran, may be trained or developed on the job under normal conditions of supervision, responsibility, and other working conditions through his own activity and under conditions in which his habit of work and thought may be changed and new habits and skills acquired by practice, and under conditions by which the results of the training may be tested through some measurement of output or other results.

This point of view has been adopted in certain outstanding companies and lines of business. In contrast to the training of life-insurance salesmen at a head-office school, a practice which was prevalent a decade ago, the most progressive life insurance companies are training their salesmen by having them actually practice selling, meeting the selling difficulties under normal conditions, and then learning from older and more experienced salesmen or from a supervisor the best methods of dealing with them. The salesman finally acquires new habits and skills which he applies with success, and to his own financial benefit as well as to that of his company. Such training must naturally be given by the supervisor in a branch office or agency.

Successful Results of Decentralized Training. In practice this policy has greatly reduced turnover or failure of salesmen, has increased the output and earnings of salesmen and the profits of the companies, and has usually resulted in a rapid expansion of the total volume of business done by the company.

In other lines of business the same practice applies in the training of office employees—stenographers, clerks, bookkeepers, etc. Banks, for instance, have pretty generally abandoned the formal classroom method of instruction and are training their new and older workers on the job under a supervisor capable of training the new employee or one who is marked for promotion.

In several electrical, telephone, and manufacturing companies, the same practice of decentralized training has been adopted, especially by large companies which formerly were wedded to centralized training by an educational department.

This trend in the training of employees in America will not be successful if not accompanied by a complementary program of training supervisors to train, which, after all, is rapidly becoming the most important part of a training program in American business.

Not all supervisors, in fact very few, are born trainers, but it is equally true that very few supervisors are incapable of becoming good trainers. In any case, it is quite true that there is no supervisor who ought to be one whose technique of training his immediate associates cannot be improved. Even those supervisors who are best equipped naturally to train employees can acquire better habits and skills in actually training them.

The central point in training employees within companies is the training of supervisors to train. One of the largest electrical companies in America has practically done away with all formal classroom instruction of employees and is concentrating its efforts on training the supervisor to train. The syllabus of the supervisors' training program consists largely, practically 90 to 95 per cent, of material which deals with teacher training, the assumption being that in order to make the training program really effective, steps must be taken to make the training of the employee continuous from the time of entering the business until he leaves it, and on the principle that the best training is that which is given in connection with actual work under normal circumstances of supervision, incentive, and responsibility.

Preparation of Instructional Material a Most Important Step in Training Program. The preparation of instructional material is, of course, one of the most important steps in a training program. At one time the usual practice was for the instructor himself to learn every element of the job and then proceed to convey the information to the employee, usually by the lecture process in classroom. More recently, emphasis is being laid on the job difficulties of the employee, and the result has been a pronounced movement in the direction of analyzing the job and the learning difficulties of the employee, and setting up the order in which the latter appear. Out of this analysis it is possible to formulate a body of instructional material which attacks, not training for the whole job, but rather training the employee to overcome the job difficulties, and to set up a learning order which will, so far as possible, solve the worker's job difficulties in natural sequence and, so far as possible, as they appear in his daily activity.

In the preparation of instructional material it is generally conceded that the supervisor who should do the training ought to have a share in preparing its outlines. In fact, he ought to have a share in preparing the whole training program. This is more or less a matter of tactics in order to enlist the whole-hearted cooperation of the supervisor by making him feel and believe that it is not simply a program superimposed on him. Furthermore, his participation in the preparation of the training program and the instructional material is a very effective part of his preparation for the training process.

In the training of supervisors to train, the same principle applies as in training the rank and file of employees. Here again practice makes perfect, but supervised practice is much more likely to bring perfection than unsupervised. The alternative is that supervisors who undertake to train are as likely to become habituated to useless or ineffective practices as they are to acquire the more skilful ones.

This point of view simply parallels the general accepted principle of training public-school teachers to teach by giving them supervised practice in schools of education or in normal schools for teachers. Its effectiveness where the plan has been used in business is well vouched for, and it is rapidly superseding all others.

An important step in a modern training program for employees which accepts the principle of decentralized training by the supervisor is an analysis of the teaching process in terms of difficulties of the supervisor or department head in training his employees on the job, for the job. Such an analysis leads to the development of a body of instructional material on the technique of training.

Actually, it has been found by some companies that it is well to present a number of successful methods of meeting such job difficulties, recognizing that different persons may need to use somewhat different methods, especially with different types of employees. This practice has the additional advantage of removing what is frequently a supervisor's alibi, namely, that he has tried a recommended practice and that it has not been successful. To such a supervisor the obvious answer is that "other methods have been suggested—try them. All of these methods have been successfully used by some supervisor. Find the one which for you will be successful, or invent a new one which for you will be effective."

There is implied in this answer the alternative that the supervisor in question may not be entitled to hold the position of supervisor.

Functions of Educational Director under a Program of Decentralized Training by Supervisors. What has happened to the educational departments or educational directors of former days? A very large number of companies still have what is commonly referred to as an educational or training department, or an educational director or manager of training activities.

There are no definite signs that the number of such departments have decreased or that they ever will decrease. The men who held such positions have in some instances been transferred to other work in or out of their companies. Other directors of training activities of former days have themselves grown and changed their points of view and aligned themselves with modern training trends.

It may well be asked, What is the function of such an educational director or manager of training activities under a program of decentralized training by the supervisor on the job for the job?

The best practice of today recognizes the following functions of such a department:

1. To provide that enthusiasm and promotive quality which spreads interest in training throughout the organization and creates desire and willingness on the part of every supervisor to take part in the training process.
2. To help to prepare the instructional outlines to be used by supervisors in the training of their workers. One says "help" advisedly, because it may be easily recognized that when the supervisors themselves have prepared the instructional outlines with the help of an educational department, they are much more likely to take an interest in the training program and to feel a definite responsibility for making it effective.

3. To prepare, improve, and constantly revise the procedure for carrying out the training program, thus facilitating the work of the supervisor.
4. To take a very active part in training the supervisor to train.
5. To act as an adviser to the management of the company in regard to the development of its personnel, and thus link the training policy of the company to the whole future of the business and its financial success.

Time was when educational and training departments were usually set apart from other personnel activities. A training department was paralleled by an employment department, an industrial relations department, a welfare department, a health department, etc. This stage of thinking about training and personnel administration in general was a period during which there was a National Association of Corporation Schools and also a National Association of Employment Managers. It assumed that one department employed people without any responsibility for training, and that another department trained employees without any responsibility for selection and without responsibility for output.

In 1922 these two associations were merged as the National Personnel Association, because it became evident that personnel administration is essentially a unit; that employment, training, placement, transfer, and promotion, and even compensation, are all different phases of the same problem. The effort to train employees who are not adapted to the work is fruitless and a waste of energy and funds.

But progress was not yet over. By 1923 it had become evident that personnel administration is an integral part of management, that every supervisor and every executive must devote himself to a very great extent to personnel problems. As Oscar Grothe, vice president of the White Sewing Machine Corporation, who is very active in the training programs of his company, says, there is in reality no personnel problem—there is only a management problem.

The consequence was that in 1923 there was a further change of name to the American Management Association, which organization devotes more attention than ever before to problems of personnel, including the training of employees. It is now quite clearly recognized that training is a management problem, not simply a management problem which may be delegated to a training department but rather one which is the responsibility of every executive from president down to the last supervisor, and which executives may solve most effectively with the help of a personnel department in which there will probably be found, on the average, a director of training activities.

If we accept the point of view that management is in large measure, 80 to 90 per cent, a training job the natural corollary is that men selected to direct training activities should possess or acquire in unusual degree not only a knowledge of the business but of instruction and training. Business executives would not place in charge of sales or production, nor be advised by, men who were novices in these affairs, who did not know sales or production technique well. It is not less important that sales or production supervisors be guided in training matters by men skilled in commercial, industrial or other vocational training. It is not wise that educational or training directors should obtain their specialized experience at the expense of the supervisory

organization. We should not continue to select "likely looking" fellows from the organization or import academically experienced teachers in whom to entrust the supervision, advice, and guidance of this 80 to 90 per cent activity.

The trend toward decentralized training by supervisors places different requirements and more responsibility upon training directors than occurred under formalized school training in business. The modern training program is infinitely closer to production, distribution or office management than heretofore. This type of training goes further than gathering statistical or descriptive data in subjective form and disseminating it informationally. Classroom activity becomes somewhat antiquated. Rather it demands analysis of general and specific situations in which training is needed. These must be studied objectively to determine the result to be gained from the training. This is an engineering job equal in status to safety, production, sales or any other phase of management engineering. It is not a school-master's nor schoolroom job.

Only one step is involved in teaching the supervisor to teach. This alone will not constitute a training program. Thirty or forty hours supervisory training does not remodel a supervisor permanently. We cannot rely on evangelistic treatment without expecting backsliders. There must be continuous training over a period of years for real effects. Supervisors who have been taught to teach cannot be expected to observe all the training possibilities in the jobs they direct. Experience shows they do not anyway. The training director ought to have a "nose" for these possibilities. A training program not built upon them will fall short.

If we accept the 80 to 90 per cent training viewpoint what of the effect upon costs through following an ill designed program? Can this training manager do less to effect costs than the production manager or the sales manager? Are we as careful in the selection and training of the training manager as in training either of the other two managers? If this man is to be responsible for gearing up the training efficiency of line and staff supervisors he must know his training theory and practice.

Supervisory training has responded to active thought in the past ten years. It has been the greatest factor in the change which has occurred in industrial training. Success would have been greater had it not been so difficult to obtain men who understood the technique of supervisory training in a practical way. There is need, urgent need, to train more of these men, directors of training, men who can promote the practical application of this activity as a management function.

From a stage when education of the worker was in large part a function of the master craftsman and training of the workman entirely so—the master craftsman, however, being ill prepared to teach except in terms of the master-ship of his craft—we have progressed through a stage of formal classroom instruction of employees, partly for educational and partly for training purposes—a period of mass production in training—to one where the educational and training work of companies is being confined largely to training for the job, on the job, by a supervisor who has been trained to train.

Employee training has thus come to be recognized as a management problem, and the stage has arrived where the subject of training employees takes a very large place in all discussion of management activities.

CHAPTER VIII

MEETING THE HAZARDS OF THE WORKER

PERSONNEL HEALTH SERVICE

BY R. S. QUINBY, M. D., *Manager Industrial Relations, Hood Rubber Company, Inc.*, and WILLIAM H. LANGE, *Director, Industrial Relations Service, Policyholders Service Bureau, Metropolitan Life Insurance Company*

One of the more recent developments in the field of industrial relations has been the growth of health and sanitation measures for the protection of employees. Being somewhat less directly related to increased profits and such personnel activities as employment, accident prevention, and training, they have found a place in business organizations more slowly. Previous to 1910, personnel health service was practically unknown. A few firms, when installing extensive welfare programs, included medical service to employees. Others located in remote communities found it necessary to provide medical service, and frequently to take responsibility for community sanitation. Some companies engaged in hazardous operations were forced by necessity to establish medical departments to care for accident cases. A few employers, recognizing the relationship between health and operating efficiency, introduced various health measures, particularly physical examinations.

The enactment of workmen's compensation legislation in the years immediately following 1910 was the greatest single stimulus to the introduction of health and sanitation measures. These acts required employers to provide medical service to those injured while at work. Consequently, medical departments were established in many large organizations. Eventually, many of these first aid departments extended their services to include health activities.

Out of the need of business for physically competent workers and the need of employees for trustworthy medical guidance, a new attitude toward personnel health service has developed. Employers, either alone or in conjunction with workers, have introduced in hundreds of establishments medical service which they believe a necessary detail in the proper conduct of their business. They have come to recognize the relationship between healthy workers and accidents, production, and costs. Medical service has been extended to the point where it is being rendered to hundreds of thousands, even millions of workers. Health activities have developed beyond the experimental stage and have become firmly established as a necessary part of the personnel program.

Functions. The functions of the individual medical department vary to a considerable extent. The size of the organization and the type of business to a large degree determine this. Obviously, the small company cannot afford a too ambitious medical program. Companies engaged in less hazardous lines of business do not require so complete a service as those which involve operations dangerous to health and limb. Dr. W. Irving Clark of the Norton Company has summarized the scope of functions of a fully developed health department as follows:

1. The physical examination of all applicants for positions.
2. The reexamination of all employees transferred from one department to another.
3. The periodic examination of all workers employed in departments where there is a health hazard.
4. A periodic examination of all workers who have physical defects needing follow-up.
5. The placing of physically defective workers in departments where the work will not prove injurious.
6. The diagnosis and, in certain cases, the treatment of workers applying to the dispensary for medical care.
7. Cooperation where possible with the family physician of sick and defective employees.
8. Diagnosis and treatment of workers injured during employment.
9. Diagnosis and in some cases treatment of workers having surgical conditions not the result of employment.
10. Spreading health publicity by lectures, leaflets, and similar publications.

Status of the Medical Department in the Organization. Opinions differ as to the proper status of the medical or health department in the organization. Some firms prefer to assume that health service is so much a part of the personnel program that its supervision should rest with the personnel or industrial relations department. Others believe that since this activity involves professional knowledge, it should be separated from other personnel functions and assigned to a separate department of its own. A few companies have solved this problem by placing under the supervision of a doctor the entire personnel program, including medical service.

The extent and character of the health service determine which method is preferable in each individual case. If the health department is to be confined to a limited field of activities, it is very logical to assign supervision of it to the personnel department. However, where circumstances warrant particular emphasis upon personnel health service, the medical department may be recognized as a special unit apart from the personnel division. In any event, provision should be made whereby the medical department is consulted on all matters which bear directly or indirectly upon the health of the working force.

Staff. Obviously, the size of the organization and the scope of activities undertaken by the medical department determine the staff necessary to conduct personnel health service. In small units, plant nurses appointed to care for accident cases often are called upon to render health service. Contrasted with this are the elaborate medical departments maintained by many large corporations to care for the health of employees.

The simplest form of health service is that rendered by the plant dispensary nurse who finds time to attend to health cases in addition to her accident duties. Naturally, she is restricted in the scope of work which she may perform. She may not diagnose or prescribe. She may merely attend to emergency cases. Frequently, she is assigned the supervision of plant sanitation, particularly the inspection of work places, toilets, wash rooms, and recreation rooms.

In addition to dispensary nurses, some firms employ special nurses for outside visiting duty. These nurses call at the homes of ill employees and render such service as they are able to give and the employee may desire. Their particular value lies in the fact that many cases of illness may be treated by the nurse to such good advantage that the ill employee is able to return to work sooner than if no attention was given him.

The next stage in the development of a medical staff usually takes place with the appointment of a part-time or full-time physician. A variation of the former is the physician on call, that is, the physician in private practice, who is available on call for visiting industrial cases of illness. Full-time physicians are to be found in increasing numbers in large establishments. Part-time physicians and physicians on call usually are employed in the smaller organizations which have no need for the entire time of a doctor.

Often, various types of specialists are associated with industrial medical departments, either on a part-time or full-time basis. In many cases, these men are employed by firms having peculiar health hazards which require special medical service, such as those relating to chest affections, skin diseases, and throat conditions. These specialists usually are engaged in a consulting capacity and attend to those cases referred to them by the plant medical department.

Growing recognition of the importance of healthy teeth and satisfactory vision has led many organizations to provide the services of dentists and oculists. Others, such as department stores, employees of which find it necessary to be on their feet a large part of the day, provide the services of chiropodists and podiatrists.

Medical Dispensary. The location, size, and equipment of medical departments depend upon several factors, among which are the number and type of employees, the scope of health activities, and the location of the firm with respect to adequate community, hospital, and medical service.

Individual conditions determine to a large extent the most desirable location for the medical dispensary. The dispensary should be set as nearly as possible adjacent to the department that may need its services most frequently and quickly. When the activities of the medical department include physical examination of the workers and of applicants for employment, it may be advisable to have the department readily accessible to or directly connected with the employment department. If both men and women are employed, it may be preferred to provide for the separate use of equipment or to maintain separate dispensaries. If the organization is scattered over considerable space or if there are special hazards in different parts of the plant, it may be necessary to establish separate medical stations at convenient locations, these being under the direction of a trained nurse assigned by the medical department.

Although satisfactory work may sometimes be accomplished in small quarters, it is important not to handicap medical departments by assigning them inadequate space. The Conference Board of Physicians in Industry after careful consideration of the question has established the following minimum requirements for the size and equipment of an industrial dispensary:

A first-aid room should be not less than nine by twelve feet in size, should be well lighted and ventilated, should have running water—hot as well as cold, if possible—should be provided with toilet facilities in or near the first-aid room. The light should be particularly good at the point where first-aid service is to be rendered, where an adjustable electric lamp would be very serviceable and convenient. Aside from ordinary good ventilation, it is desirable to arrange for a large inflow of air by fans or otherwise, to stimulate patients when feeling faint. The ceiling and walls should be light in color and frequently cleansed.

The room should contain at least the following equipment:

One metal combination dressing table with drawers to hold instruments and dressings.

One metal chair with head and arm rest.

One metal stool built in combination with metal waste can.

One small wooden or metal examination table with pads, with ends hinged to drop down.

One stretcher, of the army type (canvas stretched over two round wood poles) or one of metal.

One small instrument sterilizer arranged for electric, gas, alcohol, or kerosene burner.

One-half dozen utensils, such as arm and foot basins, three- or four-quart ordinary basins, two-quart dipper, bed pan, etc.

One portable first-aid outfit.

Appropriate instruments, including razor, dressings, splints, drugs.

This equipment will be found generally suitable in small organizations for the treatment of minor cases. It is inadequate, however, to care for the larger number of cases usually encountered in larger establishments. Increase in facilities depends on the growth of the organization and the extension of the medical service.

The arrangement of the equipment in the industrial dispensary depends largely upon the preference of the individual in charge. In general, three types of arrangement are used. The first method employs a single large room in which all treatments are made. Patients usually are seated around the room, the physician and nurse attending each person in turn. Necessary dressings and medicines are carried from patient to patient. The second method utilizes a single room for dispensary purposes, but the equipment is localized in units for the treatment of specific types of cases. Thus, the equipment and appliances used in the different types of medical work are kept together. The third method provides a waiting room and a consultation office where injured or sick workers may be examined privately by the physician. Aside from the fact that it assures privacy, the last named type of dispensary probably is the least desirable. Most cases coming to the dispensary for treatment are suffering from minor conditions and there is little reason for privacy in rendering medical attention.

Scope of Activities. Personnel health service usually involves the following activities, emphasis being given to those which the individual firm believes most important to its particular groups of employees: physical examination, treatment of injuries, diagnosis and treatment of illness, health education, and control of working conditions and sanitation.

Physical Examination. The development of preventive medicine has brought a general recognition of the importance of the physical examination. Without knowledge of the physical condition of the individuals whose health is to be conserved or improved, it is difficult, if indeed not futile, to develop the facilities required for their care. There are two types of physical examinations: the preliminary examination of the applicant for employment and subsequent examinations at regular or irregular intervals during service with the organization. Both types of examinations are so different in purpose and method that they may be treated to a certain extent as distinct from one another.

The physical examination of applicants for employment is designed to protect the organization against the introduction of contagious diseases, against the employment of workers so handicapped by ill health or physical defects as to be a menace to themselves or to fellow workers and against false claims of injury after employment. It is further essential to the proper placing of workers in positions for which they are physically qualified. From the employee's point of view, the employment examination may furnish information which may serve as a basis for the correction of physical defects or faulty habits of life.

In order to obtain the maximum value from the physical examination, it should be conducted in a manner that not only enables management to fit a workman to a suitable job, but also reveals the information requisite providing for the maintenance of health to the end that he may continue on his job effectively.

The following list represents the Examination Standards in Reference to Physical Defects Necessitating Special Attention drawn up by the Conference Board of Physicians in Industry:

Special senses:	Eye
	Ear
Heart:	Valvular disease
	Tachycardia (Rapid heart)
	Arrhythmia (Irregular heart)
Lungs:	Tuberculosis (Consumption)
	Emphysema
	Asthma
	Bronchitis
Hernia:	Inguinal (Groin)
	Umbilical (Naval)
	Femoral (Below groin)
Limbs:	Contractures
	Enlargement
	Flat feet
	Atrophies (Wasting)
	Varicosities

Vessels:	Arteriosclerosis (Hardening of arteries) Varicose veins
Genitals:	Orchitis (Inflammation of testicle) Epididymitis (Inflammation of cord) Varicocele (Varicose veins leading to scrotum)
General:	Rheumatism, nephritis (Bright's disease) Alcoholism Syphilis Diabetes Skin, and other diseases
Spinal:	Tabes (Locomotor ataxis) Multiple sclerosis Multiple neuritis
Deformities:	Atrophies (Wasting) Hypertrophies (Enlargement) Contractures Curvatures.

All second degree defects should be considered as substandard according to the following schedule:

Hernia (2d degree or more).
Varicosities (2d degree or more).
Flat feet (2d degree or more).
Varicocele (2d degree or more).
Hearing (2d degree or more).
Vision (2d degree or more).

Also the following:

Arteriosclerosis.
Endocarditis.
Tuberculosis.
Bronchitis.

If large numbers of women are to be examined, a female physician is desirable for this purpose—even on a part-time basis. The same consideration should be given workers as would be accorded private patients in the physician's office. This is the first contact between the employee and the health-work program in industry, and every effort should be made to acquaint the worker with his condition and encourage him to consult the physician as future needs arise.

Reexaminations. As in every enterprise, there is not only the original creative work but the job of maintenance as well. This takes the form of reexaminations for the purpose of checking up existing conditions, or of discovering the development of new conditions. A desirable program of reexamination may be pursued among the following divisions of the personnel:

1. The management.
2. Substandard workers.
3. Workers exposed to industrial hazards.
4. The remaining employed group.

The management, being the most vital to the success of the concern, offers the most fertile field for constructive health work. The most important

members should be examined every six months and the entire management yearly, and the necessary preventive and reconstructive treatments instituted.

Substandard workers should be reexamined at such times as the individual needs of the case indicate. The physician making the initial examination will quickly ascertain when a reexamination will be desirable, and should establish a record system which will automatically bring this case to attention at the proper time.

Workers exposed to occupational hazards should be reexamined according to requirements of the particular situation. Much authentic literature deals in detail with various occupational diseases and will serve as a guide for the unacquainted in laying out their program.

Whenever practical, it is desirable to reexamine the remaining group yearly. If, for good reasons, this is impossible, the initial examination of applicants and reexaminations, according to the above schedule of those in the management, subnormal workers and workers exposed to industrial hazards will secure a large proportion of the benefits to be derived from physical examination. It is to be remembered that through dispensary visits on account of sickness or accident, opportunity is presented for the casual examination of a large number of workers.

Some Common Questions. What is the best way to start the physical examination program? There may be several best ways, but certainly one point is fundamental. That is, the manager of the enterprise must be "sold" on the merits of this work. This places squarely on his shoulders the responsibility of leadership and example. He and his management organization must willingly and gladly submit to examination, and cooperate in influencing others to follow this example. If the management is not convinced of the wisdom of this work it would better be left undone, for workers will quickly sense the insincerity of something offered to them but not good enough for their superiors. Granted an agreement among the management of the desirability of beginning physical examinations, they should be the first to submit to the examination and follow the advice furnished. Next, older employees from the different departments may be selected, and then applicants for work, and finally the entire remaining force. Under certain conditions it has been found satisfactory to begin the examination work with applicants and gradually extend it to the employed force.

Frequently, there is seen in the management a lukewarm belief in the desirability of physical examination, but a fear that some untoward happening will result if it is actually attempted. Most of us have passed through this state and have later been surprised and chagrined to see how little real difficulty developed. Given the right management attitude and example and an industrial physician with good common sense and ability, nothing but useful and satisfactory results will follow.

What about those who are rejected or found suitable for only limited employment? This is a less serious problem than might seem at first thought. Over a period of years in many plants, the rejection rate has been slightly over 5 per cent. It is ordinarily simple for the examining physician to show a man why he is incapable of doing available work in the plant. Sometimes, the cooperation of the family or a consulting physician is desirable. Then,

too, prior to employment, we are no more obligated to employ a physically unfit man to do manual labor than we are to employ a man unable to do simple arithmetical calculations for accounting. This is one advantage of making examinations before or during the process of hiring.

Great insight and knowledge, both medical and of plant operation, is required to intelligently place those who have definite physical defects in work which will enable them to safely earn a livelihood and give to the enterprise a profitable return. This is one of the greatest constructive services resulting from physical examination and requires, as has been stated, an intimate knowledge of plant operations and the cooperation of the Employment Department.

What does physical examination work cost? This will differ considerably under varying conditions. If the volume of work is sufficient to occupy a full-time physician, the cost will be nominal—probably less than \$1 per examination. On a part-time basis in a smaller factory the cost can be made very low. In fact, under almost any conditions some plan can be worked out, if the service is really desired, on such a basis that the cost will not be prohibitive.

Treatment of Injuries. The major activity of medical departments, particularly in the case of industrial firms, is the treatment of injuries arising as the result of accidents occurring in the course of employment. Broadly speaking, injuries of this type may be classified into three groups—trivial, moderately severe, and severe. The method of treatment differs in each. Trivial injuries, by far the largest number, usually can be treated by the dispensary nurse under the supervision of one of the medical staff. In the case of more common injuries, it has been found more convenient to develop a standardized treatment and to have on hand standardized equipment and medicine ready for the care of all such cases.

Dr. Clark suggests the following standardized treatment:

Lacerated, incised, and abraded wounds.

1. Cleanse part freely with gasoline, using sterile gauze.
2. Wipe out wound thoroughly with cotton applicator dipped in gasoline.
3. Paint wound thoroughly with iodine, using a cotton swab applicator, or spray iodine into and around wound.
4. Apply sterile gauze compress.
5. Bandage.
6. Reinforce bandage with adhesive plaster strips.

Sprains.

1. Shave.
2. Bandage.
3. Transport to doctor.

Burns.

1. Cleanse gently with saturated solution of soda bicarbonate.
2. Apply 3 per cent soda bicarbonate ointment or in mild cases powder with compound stearate of zinc.

3. Apply dry sterile dressing held in place by a not too snug bandage.

Strains (back).

1. Strap using straps three inches wide.
2. Bake with electric heater.

Fractures.

1. Put injured part at rest by immediate immobilization in appropriate splint.

2. Summon doctor.

Haemorrhage.

1. Paint rapidly with iodine.

2. Apply mass of three- by three-inch sterile gauze compress held snug with bandage.

3. Splint.

4. Apply tourniquet only if absolutely necessary.

5. Summon doctor.

Eye injuries.

1. Flood eye with 4 per cent boric acid solution.

2. Wipe out loose particles with sterile cotton swab on applicator.

3. In case injury is severe or if foreign body is imbedded in cornea, drop castor oil freely into eye, apply sterile gauze, bandage loosely, and send to physician.

While trivial injuries can be safely treated by a specially trained nurse, all cases of moderately severe injuries should be seen by a doctor at once. The efficiency of the first treatment and accuracy of diagnosis plays a most important part in the rapidity of recovery.

Severe accidents require the immediate attention of a doctor. First aid should be given the patient at the point where the accident occurs, but this should be of the simplest type. Transportation to the dispensary should take place under a doctor's direct supervision. Further treatment of the case, whether at the dispensary or at the hospital should be at the direct supervision of the head of the medical department.

Diagnosis and Treatment of Illness. The gradual extension of compensation acts to include illness arising from occupational hazards and wider recognition of the direct relationship between health of employees and efficient operation have been responsible for the introduction of health service in many companies which have a medical department. However, opinions differ as to the extent to which health service should be provided. In the past, private practitioners have questioned the right of the employer to provide medical attention to employees who have become ill in the course of employment. In recent years, this objection has diminished. There is evidence that the supposed encroachment of industrial medical activities upon the private practice of outside physicians is more apparent than real.

A primary object of the medical department should be to prevent as much sickness as possible. Therefore, it should also treat minor cases of illness which would not otherwise receive medical attention and should give emergency treatment and advice in cases of sudden illness. In addition, it should cooperate with the family physician carrying out any suggestions made by him as regards change of work or other matters which are under its control. In providing this service, employers should be careful to assume no special obligation to care for employees beyond the provision of reasonably sanitary and healthful working conditions and treatment of illness arising from employment.

The scope of this service will generally have to be determined by the type of medical and hospital service available in the community. In the case

of firms located in small towns, the company dispensary may easily become a medical center at which X-ray and laboratory work can be done at a trifling charge for the doctors in the community. Employers in large cities have no need to provide such complete service. Their medical departments should be confined entirely to the treatment of trivial sickness in an effort to prevent the development of more serious illness, cases of the latter being referred to private physicians.

Health Education. An important influence upon the health of the individual employee is the care which he himself devotes to the safeguarding and maintenance of his health. Repeated contact with the medical department acquaints him with simple methods of preventing and relieving illness. Usually this is the initial form in which health education begins. Health education campaigns beyond this take numerous forms. The more common programs include the following: group conferences, posters, bulletins, articles in employees' magazines, motion and stereopticon pictures, classroom instruction, and demonstrations. No matter what combination of these is introduced, it must be borne in mind constantly that the most effective health education is that which arises out of the contact established every time an employee visits the medical department for treatment.

Control of Working Conditions and Sanitation. To be complete, the program for health conservation must include close supervision over working conditions. While remedial action usually rests with management, responsibility for providing healthy working conditions should be assigned to the medical department. This should include such items as illumination and ventilation. In addition, the medical department should be responsible for control of special industrial hazards such as dust, heat, humidity, and poisons.

Cleanliness of workrooms, washrooms and toilets, lockers, and the plant generally is largely a matter to be attended to by the workers engaged for that purpose. The general supervision of this work, however, may properly be at least under the advisory control of the medical department.

Diseases resulting from physical working conditions or the use of chemicals incidental to manufacturing are coming to occupy an important place in industry. These cases, in themselves, in some plants demand much technical knowledge, as well as having an effect on the program of physical examination, remedial treatment, and compensation insurance.

A careful study on the part of the industrial physician of any processes capable of causing occupational diseases is required. He must know the causative agents, methods of preventing or minimizing the hazards and the proper treatment and relation of such cases to compensation insurance. For detailed information on this subject one may be referred to Kober and Hayhurts, "Industrial Health."¹

Medical Records. The personal preference of the head of the medical department usually determines what medical records shall be maintained. Consequently, wide variation in forms may be found in industry. In general, however, the following records are kept:

1. Daily log of medical treatments.
2. Individual record of medical treatments.

¹ P. Blakiston's Sons & Co.

3. Report of physical examination.
4. Monthly report of medical department.

In most cases, the first two are comparatively simple records. As employees are treated by the medical department, record is made upon a daily log. Data entered includes notation of the employee's name and check number and a brief description of the diagnosis and treatment. At the close of each day, this information is posted to individual records of medical treatments. The American Association of Industrial Physicians and Surgeons recommends two forms, either of which may be used for this purpose. These forms are shown in Figs. 1 and 2.

Industrial physicians differ as to the preferable form for recording data secured as the result of the physical examination. One group prefers a record

similar to that in use at the Norton Company (Fig. 3) since this gives the examining physician an opportunity to record in detail all facts concerning specific conditions. In contrast, another group favors a form such as that used by The National Malleable Castings Company (Fig. 4). This record makes use of the check list and diagrammatic methods for indicating conditions and thereby simplifies the recording and summarizing of results. Both types of report have merit. The choice as to which shall be adopted rests with the individual organization.

In order to present a monthly summary of the activities of the medical department, a record similar to that compiled by the Medical Department of the Eastman Kodak Company (Fig. 5) may be used.

department. The knowledge that these records are kept confidential will help greatly in securing the cooperation and goodwill of the working force.

Medical Sociology. Already several new relationships, both within and outside the plant, have been suggested. It is perhaps desirable to enumerate

more definitely some of these activities which may be developed into opportunities for furtherance of the health program.

The first of these grows within the plant through such media as the Mutual Benefit Association, athletic organizations, foremen's meetings, and shop committees.

FIG. 4.

If the physician in industry is really awake to his opportunities he will identify himself with such activities and will use them as a means of instruction in health and hygiene and for developing interest and cooperation in

this field. The Mutual Benefit Association is a particularly fertile field for such constructive work.

Outside the plant, the most common and useful method of creating helpful service and influence is through home visits, usually on occasions of absence from work. Many companies have found it profitable to investigate absences and follow up cases of disability caused by sickness and accidents. Some few companies have seen fit to attempt the medical treatment of employees and their families in their homes to a very inclusive extent. Such a step is rather advanced and while under certain local conditions it might be wise,

FIG. 4 (Reverse).

generally speaking, industrial medicine has not yet attained a point of development where such practice would be advisable.

Considerable reduction in general absence and much constructive assistance in shortening disability has been frequently accomplished by the home investigation of absences by nurses, supplemented in some cases, by the industrial physician. These visits may be made on the second or third day of absence and revisits to those disabled as may be indicated. These visits should never savor of "policing" but should be made into opportunities for constructive health work and a reasonable audit of personal absences. If properly done, they will not be resented but, on the whole, welcomed.

The physician in industry may, with much advantage to himself, his company and the employees, identify himself with civic and professional

organizations in the community. The local medical society, the Red Cross, the antituberculosis association, the district nursing association, and the

local public health work are all fields allied with his, and his associations with such endeavors may well prove useful.

As has been mentioned, the relationship of the industrial physician with the practicing physician is extremely important. With proper care and effort, desirable working arrangements can be created and maintained. It has been found helpful, in order to acquaint practicing physicians with factory conditions of work and with the aspirations of the industrial physician, to invite groups to the plant, showing them the work being carried on and outlining the policy governing the work. Their attitude with employees and toward the medical work in the plant is sometimes materially changed as a result of such visits. This problem of the industrial physician requires much patience and constructive effort but results will make it well worth while.

The enumeration of these various correlaries to the practice of industrial medicine suggests that the opportunities for useful influence by the industrial physician are manifold and make for accomplishments beyond the original conceptions of the field of industrial medicine.

Costs of Health Service. What will be the cost of such a program of health supervision as has been outlined? An investigation made by a committee from the Associated Industries of Massachusetts among 90 leading manufacturing plants indicates that these plants are spending three-tenths of 1 per cent of the factory pay roll for health supervision.

An investigation made by the National Industrial Conference Board, indicated that in 207 plants, employing 764,247 workers, the average annual per capita cost of health supervision was \$4.43.

Obviously these cost figures are of general interest only, but they do point out that the cost of such service is very nominal and considering the potentialities for saving and service may well be a paying investment to an industrial enterprise.

Measure of Accomplishments. Too often in personnel activities no definite effort is made to measure accomplishments. Sometimes, too, we lack a yardstick. This is not true in industrial medicine. Simple records and small clerical effort will tell us the results. These are best interpreted as days lost yearly on account of sickness and accident. In some cases, efforts have been made and results secured in determining in much detail, reasons for sickness, incidence according to age, occupation, sex, and physical condition. There is a rapidly growing attempt to collect such information and to create it in such terms as to be comparable with the experiences in other plants. Such a scientific effort toward the measurement of accomplishments in industrial medicine hardly needs commendation. Useful information and assistance in this field may be secured from the Statistical Office of the United States Public Health Service.¹

Results. Business executives will rightly question what results may be expected from such a program as has been outlined. Detailed experiences would be inappropriate, but certain general statements based on broad experiences will be helpful. In a business with a reasonably representative personnel as regards age and sex, with no outstanding occupational hazards, total

¹ Treasury Department, Washington, D. C.

absence rates should be controlled at around 4 per cent of working time. This can be bettered in many incidences. Sickness disability should not exceed 2 per cent of work time. Accident disability will assume a rate dependent on the degree of hazard, the effectiveness of the safety program, the cooperation of the organization, the promptness of surgical care, and the intelligence and energy of administration by those responsible for this function. Suffice to say that the medical department can through early and proper treatment and continued follow-up of accident cases throughout disability, play an extremely important economic role in the control of accident costs. By the same token much reduction in cost of mutual benefit association, group insurance, and pension costs, may be effected. Through minimizing losses incident to absence for personal reasons, sickness and accident, a well-organized medical department can and does make a considerable economic contribution to the enterprise.

VACATION PRINCIPLES AND PRACTICES: AN APPRAISAL OF POLICY

BY DANIEL BLOOMFIELD, *Managing Director, Boston Retail Trade Board*

Like many other phases of management practice, the matter of vacations for executives, office employees and factory workers has received little intensive study. The few studies already made indicate that the vacation policies of most of our business organizations have grown up in a more or less haphazard way and are largely based on expediency rather than on a carefully worked out philosophy of management. The general feeling has been that vacations are a good thing but the explanation for that feeling varies. Some believe that vacations are justified from the standpoint of health and efficiency but believe that such vacations should be limited to the supervisory staff and office workers. Others see no justification for drawing the line and excluding routine and factory workers. Then again some see in vacations a condition in the employment relation required by custom or competition which must be met regardless of experience or other reasons for or against this practice. We can touch here only on some of the fundamentals which seem to surround vacation practice particularly with reference to executives and the supervisory staff, and briefly on vacation policy as it affects office routine workers and factory employees.

Underlying Reasons for Vacations. Undoubtedly the vacation practice began with proprietors of industry who felt the need of dropping their business responsibilities for a period sufficient to enable them to recuperate health, strength, or vigor, or for some other reason. Gradually as industrial units increased in size, this custom was extended to those associates who bore a major portion of the responsibility of the particular business and its operation. From this point it seems that the custom of allowing vacations with pay has grown through internal comparisons between jobs and competition between concerns until the present, when it is the common practice to provide paid vacations to all grades of executives and most office workers. In recent years

some concerns have extended the practice to factory employees with various qualifications.

Another version of the history of vacations is that vacations with pay in the beginning were granted during the quiet business seasons to men who were engaged in managerial or clerical work. This practice probably resulted from the fact that such men during the busy periods were required to work a great deal of overtime for which they received no extra compensation and probably tired themselves out considerably in doing this. Moreover, while they were away on their vacations the concern was put to no extra expense, for their work was usually allowed to pile up for their return.

As office forces became larger, clerical workers still received vacations with pay, and the above principles held for a considerable time. Overtime for clerical workers was not paid for, and on the whole their pay was lower than that of factory workers, so that some added incentive must be given to keep them interested. The paid vacation was the least expensive way of handling the situation since it meant that even with larger clerical forces the group as a whole carried on the work of individuals who happened to be absent on vacations and thus the concern was put to no particular expense.

The executive who puts this view forward feels that we are now facing a somewhat different situation: He continues,

The large clerical forces today are so organized that the work is as specialized on many of the jobs as those of production workers in the plant. Absenteeism among such groups means that extra people must be kept in reserve to handle the work for it cannot be allowed to hold over until the employees return, nor can the group absorb the other person's burden. It is difficult to see the justification of paid vacations for such groups of clerical workers unless such vacations are made a part of the wage contract and it is thoroughly understood that the wage is smaller because vacation money is being saved out of it.

From the strictly practical viewpoint, this executive feels that vacations are given because it is necessary to do so to attract and keep the best type of workers. Speaking of his firm he says:

This company for a number of years experimented with the plan of granting no vacation with pay to clerical workers. All clerks below the supervisory grade were hired on the hourly basis of pay, which meant that they would be paid time-and-a-half for any overtime and would not be paid for out time for vacation, holidays or illness. The wage scale was increased to compensate for the paid vacation and holidays, and the employee was expected to save from his earnings enough to cover his expenses during this period. Logically the plan seemed to be right and theoretically it should work. As a matter of fact, however, this was not the case. The clerical worker whether experienced or inexperienced seems to feel that the paid vacation is a sign of distinction and puts her in a little higher social class than the factory worker who does not receive such a vacation. The payment of money does not compensate her for this loss in caste which she suffers when she does not receive pay for vacation and holidays. Although our wage scale was higher than the average we were unable to secure the services of a large number of good prospects simply because of our policy relative to vacations. We therefore changed our policy.

We analyzed our clerical jobs and as a result of this analysis we divided them into two classes: those jobs which are so routine as to approximate factory production work remained in the hourly payment class; those jobs which require training and experience and which on the whole are such that when a person is absent the work must be either cut up by the group or left for the employee to do on his return, were paid on the salary basis of pay. By this method we got away from our difficulty of not being able to secure the best trained clerical workers, and also we hoped to stir up the ambition of the routine workers to get promoted to a job which would entitle them to vacation.

Vacations as an Aid to Health and Efficiency of Executives. While the view seems to be held by many that vacations are offered because competition for the services of clerical workers and others requires them, one cannot escape the fact that vacations are an aid to health and efficiency and this is one of the principal reasons for the vacation practice.

Let us consider the question with reference to executives and others in a supervisory capacity. Psychologists have discovered various kinds of fatigue which is not muscular but is caused by nervous strain. This is more prevalent among executives today than ever before. Judgment depends on mental and physical efficiency. These tend to become impaired by the stress and strain of modern living conditions and modern business. The greater the responsibility the greater the strain and mental fatigue.

The emotional factors in the job of an executive have not been given the full study they demand. Worry, fear of failure, anxiety as to results, pressure of duties and responsibilities, added to the fatigue brought on by physical conditions, create emotional conditions which affect an executive's work.

The antidote for this poisonous condition is a vacation properly utilized. This requires an entire change of occupation and scene, relaxation and physical activity which recreates but does not sap vitality. The element of play in vacation is essential. It is the *attitude* that counts. Physiologically, play and work are similar. It is one's state of mind that makes a vacation.

Vacations for executives should be considered in relation to the whole year rather than to the summer only. Some men need more than a summer vacation. Some again are better off in taking a vacation at a time other than the summer.

This is how one large manufacturing concern is handling the matter:

For the past ten years this company has maintained the services of a physician to watch over the health of the men in its higher executive group; this group includes, outside of the Board of Directors, such men as sales managers, merchandise managers, superintendents of manufacturing divisions and the higher executives in the office.

A study of the medical history of these men for a few years previous showed that a large percentage of them had been absent for varying periods during each year on account of illness. A careful physical examination of each of them showed that many of them were not in the condition to resist illness well. The physician felt that an increase of the regular vacation period from two weeks to three weeks plus a reduction in the number of working hours based on the individual's physical condition would mean, in the long run, that the company would get more continuous service, and service of a better

grade, from the group. The directors agreed with the principle that an executive in ill health is perhaps worse than no executive at all and decided that they would try the experiment of giving longer vacations and allowing the physician to have full rein in determining the hours which a man should work.

When the plan was put into effect there was some talk particularly by the men whose positions were just below the group selected, but that has since entirely died away. A study of the absentee records of the men in question shows a remarkable change for the better, so much so that even considering the longer vacation and shorter hours worked by many of them, the total time per year worked by the group is far in excess than was the case with the short vacation and longer hours. In addition to this, of course, must be considered the fact that since these men were in better health they were naturally more able to carry on their work effectively.

The physician who has been carrying on this work states that he found that two weeks' vacation in the case of all the executives, except those who were phlegmatic, was only enough to tone them up, but was not enough to allow them to really build up a reserve upon which they could call for the next year. He has, therefore, insisted upon the three weeks' being continuous rather than being broken up except in the cases of those men who are of such a type that short stretches at short intervals did more to restore their strength than the longer vacation. The physician is not limited to prescribe three weeks as the vacation period. In the case of men who are in run-down condition he may prescribe four weeks on occasion although this has happened infrequently.

At the end of this ten years' experiment the company is convinced that pacing the vacation policy for executives in the hands of a competent physician is a far more efficient method of handling the situation than simply one of following a hide-bound custom and establishing a policy without medical advice.

Generally speaking, the greater the responsibility the more necessary is a vacation. This is generally conceded by business. The question is how far down the line should we go. It is here that we must get at facts and experience to guide us.

Do Vacations Stimulate Better Attendance? The above question, when put to over 100 executives, brought replies which showed that in many large concerns vacation plans are not considered to have a direct bearing on the regularity of attendance. In fact, this is considered a separate problem. Some firms, however, use the vacation plan as a sort of reward for steady attendance. One large insurance company, for example, adds four days to the employee's annual vacation when the record of attendance is perfect. In some concerns, personal time (this does not include illness or excusable absences) taken during the year is deducted from the vacation period. The company claims that this stimulates better attendance records.

Here again the argument is made that vacations help to maintain the worker in a healthy condition and that the change from steady occupation offered by vacations tends to improve the attendance record.

Vacations during Shutdowns or Slack Seasons. In a number of companies vacations are given because of the necessity for a shutdown for repairs or inventory or because of slack season. One plant closes down for two weeks in August and operates with a skeleton organization. All vacations are

taken during this period. A large hosiery mill closes its plant for one week in July each year and gives its plant employees a vacation. The office and shipping room are kept open and the employees in these sections of the plant are assigned vacations on a staggered schedule. In some department stores vacations are given during January and February in addition to the summer vacations. A large manufacturer of sewing machines gives its field sales force vacations with full pay during the months from June to September.

Length of Vacation Period. Briefly summed up, the justification for differences in length of vacations of executives, office workers and factory workers is the fact that:

Executives often work longer hours than their subordinates, often giving time outside the office: the measure of their responsibility and the necessity for conserving their energy makes necessary a break in their work for rest or change.

Office workers frequently work over their regular time for no compensation—have varying grades of responsibility, generally of minor character.

Factory workers usually have definitely fixed hours of employment, and are paid (sometimes double pay) for any overtime; work is routine and carries limited responsibility.

Executives in most cases receive vacations of from two to four weeks according to the responsibilities they carry. How far habit and custom are responsible for the length of vacation period for executives rather than considerations of health and efficiency does not appear in a study of many plans. Practice varies a good deal.

One large insurance company allows its chief executive four weeks, its junior executives three weeks and the remainder of the staff two weeks. In a large manufacturing concern in the East the vacations of executives, supervisors and department heads are worked on a flexible basis and are taken when each head feels that he can best be spared. In some cases a vacation of two weeks is taken and in other cases two vacations of one week each. Department heads may take three or four days two or three times a year when most convenient, though the company does not believe that this is as satisfactory from the standpoint of rest and recuperation as are longer vacations taken at one time.

A large chain of lunch rooms has another motive for giving vacations to its executives. They want to force the executive to arrange his work so that he can leave his duties for a period of at least two weeks at a time in the hands of others. "This assures us," they say, "that in case of an emergency arising such as absence due to sickness, etc., we know that someone is sufficiently in touch with the absentee's duties to enable him to 'carry on' until the absentee returns, or other provisions are made."

In another case, a large correspondence school, a plan is in effect regarding employees who make a trip to Europe. All employees who can make a trip of this kind are allowed five weeks' pay. In addition all employees who have a perfect attendance for a month are allowed an "honor half-day" the following month. A manufacturer of drugs treats its office and factory employees alike. The length of vacation is based on length of service, the general rule being approximately as follows:

Years of Service	Vacation, Weeks
1	1
2 to 20	2
Over 20	3

In the case of executives, if they need more than two weeks "to rest up" this time is granted them.

A public utility concern makes no distinction between office and plant men as to length of vacation nor between executive and routine workers. Occasionally where executives have completed periods of unusual working pressure, short additional vacations are arranged for informally.

Should Vacation Money Be Advanced? The replies to this question received by the committee which made the 1926 study were practically unanimous against holding out vacation pay for a period to insure continuance of service. The soundness of withholding pay checks in order to insure the employees' return after vacation is questionable. Theoretically, wages or salary should be paid at the end of vacations. But in practice this does not seem to work out. The majority of employees require the money for vacation purposes. If an employee does not have sufficient loyalty to return after having received a vacation, his services would better be discontinued. As one company puts it, "We believe that service which has been rendered justifies the vacation. There can, therefore, be no excuse for withholding vacation pay."

Some concerns, however, leave this question to be settled by the employee. If he requests his pay it is given to him. In other cases the regular pay period is maintained whether this is at the end of the vacation or not.

Should Vacations Be Used as Attendance Bonuses? There is considerable doubt as to whether a vacation plan will correct poor attendance, though it may help a little. An employee may have a poor attendance record due to illness. His worth to the company may warrant continuance on the payroll and if so, a vacation is in such instances needed fully as much, if not more than where the attendance has been good on account of good health. The matter of attendance is a separate problem to be settled irrespective of the question of vacations. The use of vacations as an attendance bonus makes the reward too distant from the performance on which it is based. Attendance bonuses should be calculated and paid weekly or monthly.

Should Employees Take Other Employment during Vacations? There seems to be universal agreement that employees should be discouraged from taking temporary work during vacation time. The problem is how to do this. Various letters received by the committee were to the effect that articles and suggestions of how a vacation should be spent should be run in the house organ of the company in an effort to educate employees so that they will get the greatest value from their vacations. Here is where the employment department and the management can well take a hand in establishing the right attitude toward vacations.

On the other hand, discouraging employees from securing work during vacations seems unwise to some employers. They say that the employee's time is his own and it should be free from company control.

The facts gathered do not point to any serious problem in this direction, for very few employees use vacation time for other employment. Should a

clerical worker, for example, find means of earning additional money through manual labor such as farming or other outside work the question is whether he would not return to his regular work more fully fit than if he had spent his time on a hotel porch or had kept late hours at dances.

Another question in this connection is whether employees should be allowed to continue their regular duties during their vacation period and receive double pay. This is a practice that is universally condemned. Of course, extreme emergencies may require such work, but the better plan is to arrange for a vacation period at a later time and perhaps offer some additional reward. In any case, every effort should be made to give sufficient notice of such change in vacation period before the employee has made his arrangements.

Are Saturday Whole Holidays a Substitute for Vacations? The attitude of executives on this question is decidedly a negative one. Saturday holidays are not a satisfactory substitute for regular vacations. The week-end period is too short for complete relaxation, helpful though it may be in easing up the strain of the previous week. One firm closes its plant on Saturdays throughout the year but does not believe that this is a satisfactory substitute for vacations.

Shall Vacations Be Confined to Summer? The general opinion on this question is in the affirmative. A more satisfactory vacation can be found by the average employee at less expense in summer than in any other season. A large insurance company confines its vacation periods to the summer for the following reasons: (1) temporary employees can then be obtained most readily from undergraduates in high school and college, (2) the requirements of this company's business are such that their trained employees can best be released during the summer period. Nevertheless there are concerns which give winter vacations in addition to the others. Several Boston department stores have established this practice for executives and other workers based on length of service.

Vacations should not be allowed to accumulate from year to year. This would result in confusion and would defeat the main purpose of the vacation period.

Control of Vacations. Should increased vacation time be allowed as a bonus for taking the vacation in the slack period of a seasonal industry or of a department with variable activity? Under suitable control this may be desirable in exceptional cases. This question does not involve the fundamental principles of vacations but applies to the peculiar conditions of an industry or a business.

It will be of interest to quote the plan used by a fire insurance company:

If the seasonal peak occurs at any other time except during the summer months, the usual vacation season helps to solve the peak problem, because there is no objection to asking the employees to take their vacations during the summer months when business is slack. If the peak occurs during the summer months, as it does in our case, the vacation problem is a difficult one. The company has not felt that it could refuse to give employees vacations during the summer months, but it has taken steps to induce employees of those departments where the summer business causes a considerable peak,

to take their vacations at some other time of the year. A short time ago it was announced to the employees in certain departments where there is a decided summer peak that if vacations were taken from Nov. 1 to Apr. 1, a three-weeks' vacation would be given instead of the usual two weeks' vacation, and if vacations were taken during October and April two and one-half weeks' vacation would be given. A number of employees have taken advantage of this opportunity to obtain longer vacations. For every employee who did transfer his vacation from the summer to the fall or winter, a saving was made in that it was not necessary to obtain a temporary employee to take his place. The company could therefore very well afford to give the additional vacation during the winter when the department was not working at the highest degree of efficiency.

The departments also arrange the vacation schedule so that as many vacations as possible are taken in May or September, when the work is not so heavy as it is in the three summer months.

This control of vacations has been of considerable assistance to us in meeting the peak load problem in certain departments.

Vacations and Holidays. When legal holidays come during vacation periods should vacations be extended so many additional days? The general practice is not to extend vacations in such cases but where holidays fall immediately prior to or after the vacation period assigned, such holidays will naturally be included.

Conclusion. The practice of granting vacations to executives and office employees is well established. The reasons for vacations seem to be based on the desire of employers to improve the health and efficiency of this group. It seems to be the custom to give vacations to executives and office employees. This does not necessarily mean that, because a firm is progressive enough to grant vacations for other reasons, thus forcing other concerns to establish similar plans in competition, the real reason for a vacation plan is competition, custom or whatever you may call it. Medical science and good business sense have proved the value of such periods.

The question of how desirable vacation plans are for factory workers is still one on which conflicting views are offered.

There are and will be abuses of the vacation privilege as in everything else. The question management will have to decide is whether it can ignore the requirements of competition and the more fundamental changes in our lives which science and the growing complexity of our business, industrial and economic structure are bringing about.

Appendix 1

Vacation Plan of a Life Insurance Company

Section 1. All employees who come into the service of the company at the home office prior to Jan. 1 in any year will be allowed a vacation of twelve days. Two days will be allowed for each month of service from Jan. 1 to June 1; that is, those who come into the service in January will be allowed ten days, those in February eight days, those in March six days, those in April four days and those in May two days. Special arrangements for vacations

during the current year will be made for employees coming into the service of the company after June 1.

Section 2. *Five years of continuous service* in the home office of the company will entitle the employee to two additional holidays. Ten such years of service will entitle the employee to four additional holidays. Fifteen such years of service will entitle the employee to six additional holidays. Twenty such years of service will entitle the employee to eight additional holidays. Twenty-five such years of service will entitle the employee to ten additional holidays. Thirty such years of service will entitle the employee to twelve additional holidays.

Section 3. In addition to the above, an employee who has been with the company three months, who has not missed attendance at the office for six consecutive weeks and who has not been tardy at any session, will have an extra half-holiday for each of such periods of six weeks, earning first a morning session, then an afternoon session, alternately.

The above practices apply to clerks and unofficial department heads, although the latter are not held to a strict monitor record of their attendance.

No definite rules have been indicated for the vacations of officers, but it is the general practice for an officer to be away not more than three weeks during the year, except for the occasional four weeks' vacation of a senior executive.

Appendix II

Vacation Policy of a Large Bank

Vacation schedules should be so arranged that:

a. Only a minimum number of employees will be away at one time and vacations will be spread over such a period that the work can be handled with no curtailment of the service to customers, with a minimum of overtime, and without additions to the staff.

b. Too many officers are not away at one time, as adequate provision must be made for the proper performance of the duties of each officer during his absence.

The vacation periods of members of the official and clerical staff are as follows:

Official staff	
Vice president.....	1 month
Auditor.....	1 month
Trust Officer	
Assistant {	} 3 weeks
Vice presidents	
Secretaries	
Trust officers	
Managers	
Auditors	
Clerical staff	

Period of employment beginning prior to Jan. 1 of current year	2 weeks
Period of employment beginning during January or February of current year	1 week
Period of employment beginning during the month of March of current year or subsequently	No vacation

It is the policy of the company that no vacation period of either officers or other employees be divided.

When a pay day falls within the vacation period, salary due on that date is paid to employee when leaving. When a pay day falls immediately *after* the vacation period, salary due on that date is not paid when vacation starts, except on special written request of the department head after careful consideration has been given to the advisability of making such payment.

In the event of a resignation of a member of the staff, an allowance, in lieu of vacation, will be made on the following basis:

a. To those whose length of service has been one year or more, and who have not received a vacation for the current year..... 2 weeks' salary

b. To those whose length of service has been eight months, but less than one year, and who have not received a vacation for the current year..... 1 week's salary

Ordinarily, the above policies will apply only during the period from June 15 to Sept. 15.

NOTE. Those members of the staff who may be discharged or requested to resign are to receive no vacation salary. Two weeks' salary, in lieu of notice, is usually paid in such cases, depending upon the circumstances.

MENTAL HEALTH IN INDUSTRY¹

BY RICHARD S. UHRBROCK, *Head, Statistical and Research Department, Industrial Relations Division, The Procter and Gamble Company*

The mentally healthy individual is adjusted to his environment. He is responsive to the fluctuations in its rhythm and tempo, and finds it satisfying to adapt himself to changes that are constantly taking place about him. The mentally unhealthy person on the other hand, is out of tune with the vital, dynamic forces that are changing the world in which he lives. When these forces intrude into the retreat which he has built for himself, he is disturbed and unhappy. The mentally healthy meet life eagerly; the unhealthy are engaged in a perpetual search for peace and security in a vaguely defined world of fantasy.

We may recognize certain disturbing factors in modern industrial civilization that tend to swing the unstable worker beyond the range that we call normal. We may note certain stabilizing forces that operate to increase industrial efficiency and individual happiness. The man who is unhappy in his job is mentally ill. Some cases of such illness are temporary and recovery is rapid. Chronic cases may stretch out for years and render the individual incapable of useful work. Mental health in industry is dependent upon two diametrically opposed sets of forces. One set of factors disturbs and annoys the worker; the other set stabilizes and satisfies him. Some of the disturbing and stabilizing factors are within the control of the employer. In a sense, he is responsible for the degree of mental health, or ill health, that exists in his working force.

¹ Among the significant books and articles in this field are the following:

ANDERSON, V. V., "Psychiatry in Industry," Harper & Brothers, New York, 1920

Factors That Make for Mental Ill Health. Worry, fear, daydreaming on the job, sudden outbursts of temper, or "nervous breakdowns" are danger signals that indicate the presence of disturbing forces that are reducing the effectiveness of the individual worker. They are evidences of mental ill health. We must search beyond such facts if we are to reach causes. We may assume that the mentally ill individual has some physical defect, some digestive disturbance, or some glandular difficulty that makes him sensitive to the disturbing forces that are present in his environment. Only a thorough physical examination will reveal such causes. Actual physical fatigue, due to long working hours, may have reduced his resistance. The non-rhythmic pounding of heavy machinery may have distracted him to the point where he makes a false move and becomes the victim of an industrial accident. An unpleasant scene at the breakfast table may give an emotional coloring to the activities of the working day. Worry due to debt lowers industrial efficiency. It has been stated that, "The average wage earner, with a family, finds that he must borrow money at least once every two years to meet some emergency or unforeseen expense which cannot be paid from current income or from savings." Wage earners, with income under \$2,000 per year, have medical bills that average \$71 annually. The average funeral entails an outlay of \$363. The factor of debt, with the attendant risk of garnishment of wages and the possible loss of the job, are disturbing factors of major importance in creating unhealthy states of mind.

We have listed five factors that make for mental ill health in the industrial situation. They are fatigue, distraction, home worries, debt, and job insecurity. That list may be added to indefinitely. There are two others, however, that deserve consideration. When ambition is greater than ability, the disappointment that often results may be classified as an unhealthy mental state. This disappointment may even lead into a definite case of insanity, in which the individual compensates for his failure by building up a world of fancy in which all his dreams come true. Finally, there is no doubt but that our present system of inducting new workers into industry creates many cases of mental unrest. Learning is not a continuous process. In acquiring skills we make fairly rapid progress at first as we are taught new, simple habits. But soon there comes a time when progress seems to stop. We put forth just as much effort, but no improvement is apparent. In the

language of the psychologist, we are "on a plateau," so far as our learning curve is concerned. We are perfecting our rudimentary habits, before we can add the higher order of skills. Without doubt, many young people are "bawled out" and made extremely unhappy during this natural and necessary stage in learning a new job. Many become discouraged and quit after being assured by their foremen that "they are too dumb to learn." They get another job and the experience is repeated. Soon they come to believe that they are not quite up to par, and this mentally unhealthy attitude persists through life. They have joined the group that never quite comes through.

Stabilizing Factors. In any body of men there are stabilizing factors that operate to create a healthy mental attitude. What are the characteristics of the healthy, well-integrated worker? In the first place he is physically fit. His resistance has not been lowered to the point where worry, fears, and distractions can get a foothold. He has insight concerning his abilities and his opportunities. He does not overestimate, or underestimate himself to a marked degree. His work uses his major abilities. He has profited by supervised training, and he has acquired genuine skill in his work. His skill is known and respected by his fellow workers. He is accorded a certain degree of leadership in some field of his own choosing. He has accepted community responsibility. He is vitally interested in movements, or forces, that make his town a better place in which to live. He receives sufficient remuneration for his work to maintain the standard of living to which his education and skill entitle him; he feels secure in his job, and has a well defined life plan. He has certain regular recreations that are physically and mentally stimulating. Finally, he feels that he is making progress in his work. He knows that he will reach higher goals. He is not waging a losing battle against economic odds that are too great for him. He is in tune with his environment, and his personality is expanding.

There is no one way of insuring mental health in industry. Such a state is the resultant of many conflicting forces. The mental health in industry increases as the stabilizing factors of employment and community living outweigh the disturbing elements. Each maladjusted individual must be considered separately in order to discover the underlying causes. The employer's problem is to eliminate causes as they are noted, and to introduce as many stabilizing factors as possible into the situation over which he has control.

MUTUAL BENEFIT ASSOCIATIONS¹

BY J. DOUGLAS BROWN, *Director, Industrial Relations Section, Princeton University*

One of the most propitious developments in civilization's never-ending campaign against poverty and dependency is the increasing use of the method

¹ A study made by the Industrial Relations Section, Princeton University, reprinted by permission.

of insurance. In no field have more important strides been made than in that of industrial insurance. Group insurance covering industrial workers now provides indemnification in case of death, disability, accident, and, through endowment policies, old age. Insurance against sickness, except industrial disease, has made much less headway and it is in protecting the industrial worker against this contingency that the mutual benefit association has most to offer. The method of the latter is that of insurance, since the group protects the individual through the averaging of risks. The procedure, however, is less formal and in the past has been less dependent upon company initiative. For these reasons, mutual benefit associations date back many years, and even with the great growth of group insurance, continue to have an important place in the financial protection of employee groups.

Few individuals among a group of wage earners are sufficiently well paid or thrifty to prepare themselves or their families through savings alone against *all* the more severe misfortunes which may befall them. To do so would require too great a limitation upon the present standard of living, unless the wage earner is unusually fortunate. For this reason, the method of insurance has become widely developed. With industrial life, accident, and endowment group insurance and similar individual insurance in effect or available, the employer and employee in many progressive companies still face the problem of safe-guarding the worker against the contingency of sickness, and loss of income caused by ill health. The lower cost of the mutual benefit plan through self-imposed economy, its informality and greater intimacy, and the by-product of group feeling often developed have assured the plan a place in the industrial relations program in many companies. While group insurance may absorb the function of indemnification in case of death, which most mutual benefit plans have assumed in the past, protection against illness will probably remain a proper task of a mutual association. For this reason, the Industrial Relations Section has analyzed a group of mutual benefit plans with the purpose in mind of presenting their essential features to the industrial executive who has never participated in the introduction or administration of an association.

Rather than cover statistically the several hundred plans in existence, the Industrial Relations Section has based the following analysis upon one hundred well-developed plans from among the range available in its files. An attempt has been made to indicate the modal plan rather than discuss at length the unique features in existence in some associations. Each company has its own peculiar problems which necessitate deviation from the mode. More extensive studies such as those of the National Industrial Conference Board published in 1923 and 1924 are highly recommended for those faced with the detailed problems of organization or administration of a plan.

Provisions in the Constitutions and By-laws of Mutual Benefit Associations.

1. Purposes. The printed constitutions and by-laws of mutual benefit associations practically always state at the outset the names of these organizations and the objects for which they exist. The fundamental purpose, as it appears in these statements, is that of providing definitely stipulated payments for members in case of disability caused by sickness or accident. A large number of plans include, also, the payment of a specified sum to the

widow or other beneficiary in case of the death of a member. Mutual benefit associations are thus, to a large extent, the employees' attempt to provide protection for their dependents in case sickness or death cuts short the family income.

Other activities, however, have been assumed by benefit societies or added to their functions, and have come to be embodied in the constitutions of many as objects of the organization. The constitution of the Northern States Power Company Employees Benefit Association, for example, includes the organization and maintenance of a club to provide social, athletic, and educational advantages for its members. A similar provision is found fairly frequently. The Ohio Box Board Employees' Mutual Benefit Association includes among its objects welfare work among its members. The Wright Aeronautical Mutual Benefit Association has as an objective the promotion of all manner of educational, charitable, and benevolent activities and the encouragement of friendship among its members. The Ke-Nash-A Club, made up of employees of the Kenosha Division of the Nash Motors Company, devotes 40 per cent of its income to entertainment and the publication of the club paper. Several associations provide, either in the statement of their objects or elsewhere in the constitution, for making loans to employees. The unemployment insurance plan of the John A. Manning Company, although financed entirely by the company, is administered through the Manning Welfare Association. The Mutual Benefit Association of Pennsylvania Railroad Employees, composed of some 20,000 members, provides death and disability benefits and in addition offers a means for the purchase of Pennsylvania Railroad securities and for cooperative buying of household supplies and personal necessities. Many other examples might be added to illustrate the fact that mutual benefit associations have often come to carry on various forms of personnel or welfare work in addition to their fundamental work of providing financial relief in case of sickness or death.

2. Membership. *a. Compulsory or Optional.* Membership may be required as a condition of employment or left to the choice of the employee. There seems to be a very general feeling that it is better not to make membership compulsory, and few plans are organized on this basis.

At the same time, there is every reason why many companies are anxious to have a large proportion of their employees belong to the benefit association if one exists. First of all, membership is undoubtedly to the employees' advantage. Small as the benefits are in many cases, they are a great aid in time of emergency and without them some families would face destitution. If, therefore, the employer can encourage the members of his organization to make systematic provision for protection in this way, he is indeed advancing their best interests. The membership of a fairly large proportion of the employees of any concern is essential for the safe functioning of the association. The same principle applies here as in group insurance, that it is necessary to have approximately 75 per cent or more of the possible membership of any group in order that the poor risks may be sufficiently balanced by the good risks to make the group as a whole an average risk. Otherwise the group will be below the average, since older employees and those in poor health would be most likely to join.

Membership in the mutual benefit association is encouraged in many ways. The company frequently pays into the treasury of the association a sum equal to that paid by the employees as dues. In other cases, the association pays benefits for sickness and accident only and the company provides life insurance for members of the association. The association is brought to the attention of new employees by means of personal letters, notices in pay envelopes, publicity on the company bulletin boards, and other publicity, and it is kept before all of the employees by frequent articles in the employee magazines.

b. Age Limits. In approximately one case out of four, employee applicants for membership must be within certain age limits. The minimum ages required are generally sixteen or eighteen years, although twenty-one years are specified in a few cases. The maximum age at which employees may join, in plans having such limitations, is most frequently fifty or sixty years, although in a few associations it is placed as low as forty-five years. Instead of refusing to accept employee applicants who are over the ages specified, other associations accept them under certain conditions only, or accept them with the understanding that they will receive less than the usual benefits in case of sickness or accident. The Armstrong Cork Company limits membership to those who were under sixty when they began service with the company. The Pacific Service Employees' Disability Plan limits membership to those under fifty-five years of age except that those older may become members by passing a satisfactory medical examination. The Employees' Benefit Association of the International Harvester Company provides that employees over forty-five years of age when they join the Association will be entitled to a smaller death benefit than other members.

c. Other Requirements. In a few cases, associations are limited to white employees. In several cases, women are excluded from membership. One association excludes married women. On the other hand, the Avery Mutual Aid Society of B. F. Avery and Sons admits the wife of a member in good standing, or the widow of a deceased member, or the daughter or sister of any member in good standing. The Intertype Mutual Benefit Association accepts for membership only employees who were born in the United States or are citizens or have their first papers.

d. Waiting Period. In order to eliminate temporary employees, most benefit associations require a specified length of time before new employees are eligible to membership. Thirty days is the most usual requirement, although, two, three, or four months and even a year are required in a few cases. A waiting period between the time when the member first joins and the time when he is eligible to benefits is found in somewhat less than half the plans. Such a provision seldom applies to disability caused by accident. It protects the association in the case of members who might join in order to obtain benefits for some condition which had already partially developed.

The National Industrial Conference Board, in its study of mutual benefit associations, suggests two weeks as a reasonable period before benefits become fully available.

e. Initiation Fee. A small fee is frequently required at the time of joining. This varies in general from 25 cents to \$1.25. The Norton Company Mutual

Benefit Association, however, requires an admission fee of from \$2 to \$9 according to the age of new members.

f. Physical Examination. Upon applying for membership in the association, the employee is either (1) required to have a physical examination by a physician in the employ of the company of the association or is (2) required to furnish a statement of satisfactory physical condition from a physician acceptable to the association or (3) required to answer a series of questions concerning his physical condition, either as a part of his application form or separately.

As a protection to the association against unduly heavy disability payments, the applicant is generally required to file a statement that he has no chronic ailment or physical condition which would tend to make him a charge on the association. If he has such ailment or condition, he is frequently allowed to join by signing a waiver covering benefits for sickness resulting from it. Thus it is evident in a large number of cases that no examination is required at entrance except the employees' answers to a set series of questions or a statement from a physician. This, in connection with a waiver, may prove to be a protection to the association, but leaves the employee in the same condition as before. A growing number of associations are coming to feel that their main protection and, what is more important, their chance of service to their members lies in a program of health improvement. This includes a complete examination at the outset, followed by various forms of individual treatment or health information and advice. In a very few cases, it includes also annual or periodic health examinations.

g. Termination of Membership. In the majority of cases, membership terminates if employment with the company terminates. In such case, the employee forfeits all rights to any share in the association funds. Certain companies, however, provide that in case of temporary lay-off, the employee may retain his membership for a specified time, seldom longer than three months, if he continues to pay his dues and does not accept employment with another firm. Members of the Norton Company Mutual Benefit Association may, on the contrary, retain their membership as long as they reside in Worcester, Massachusetts. Otherwise their membership ceases, as in other plans. Members of the Employees' Benefit Association of the Phelps Dodge Corporation who leave the service of the company may retain their membership as far as eligibility to the death benefit is concerned. Members of the Jeffrey Mutual Aid Association may retain their full membership after leaving the employ of the company, and members of the Intertype Mutual Benefit Association may retain their membership by paying slightly increased dues. Such provisions are, however, comparatively rare and, for the most part, employees who leave the company forfeit their membership and all dues paid up to the date of their leaving. Dues paid beyond the date on which employment is terminated are returned. Membership may be terminated, also, by failure to pay dues for a given length of time or by attempt to defraud the association by claiming benefits when not entitled to them.

8. Dues and Other Income. *a. Members' Dues.* Mutual benefit dues are charged either (1) on a flat-rate basis or (2) on a graduated scale with both dues and benefits varying according to salaries. Where a flat rate is

used, the amount most frequently charged is 50 cents a month or 10 cents a week, but many associations now charge as much as \$1.00 or \$1.25, a month and in certain cases \$2.00. Where graduated dues and benefits are used, employees are classified accordingly to salary received or are given a choice of benefits and pay dues accordingly. In such plans the maximum salary group is generally composed of those receiving \$40.00 or more a week. This makes it possible for higher executives to help support the association without having the amount of their salaries become common property and without asking the association to pay them benefits out of proportion to those received by other members.

The same effect of varying the dues to suit wages is achieved in those plans which charge a percentage of wages. One per cent or somewhat over one per cent are the rates usually charged, but they do not apply to wages or salaries over approximately \$40.00 a week. In the Employees' Benefit Association of the International Harvester Company, dues are based on members' eligibility to benefits under the workmen's compensation laws of the states in which the company operates. If members are eligible to benefits under such laws, they pay dues of $1\frac{1}{2}$ per cent of the wages or salary they are receiving, but not over 58 cents a week. If they receive no benefits from compensation laws, they pay dues of $1\frac{3}{4}$ per cent of salaries or wages and receive correspondingly greater benefits in case of sickness. Dues for death benefits are two cents a week and are collected separately.

b. Pay-roll Deduction of Dues. In considerably over half of the plans, dues are deducted by the company from the employees' checks or pay envelopes on specified dates. This is done only after a written authorization for such action has been signed by the employee. Generally such an authorization is made a part of the application blank. In other cases, dues are paid to collectors or paid at certain specified places by a set date in the month. If they are unpaid for longer than a given length of time, the member is suspended or dropped.

c. Payment of Dues during Disability. Except in a few associations, dues must be paid during absence for sickness as well as while earning. In some cases, they are deducted from the benefits. A few groups have provided, on the other hand, that when members are absent because of disability their dues shall stop until such time as they are able to resume work.

d. Assessments. The most usual provision with regard to assessments is that if the association fund becomes less than a set amount, a limited number of assessments of not over a prescribed sum may be levied in any one year with the approval of the officers and the board of trustees or board of directors in charge of the association. At the same time, if the fund becomes greater than the set sum, dues may be decreased or omitted until the fund falls to a smaller sum. In a few plans, the prescribed limits are an average of a certain amount per member. Assessments greater than those otherwise provided for may be made in some plans upon the authorization of a special meeting called for that purpose. Whether there is any definite agreement to that effect or not, mutual benefit associations have always the possibility of receiving company aid in time of emergency and frequently do receive such aid when otherwise an assessment would be necessary. This relieves them

from the necessity of carrying as heavy reserves or operating on a basis as sound actuarially as if they stood alone.

e. Company Contribution to Operating Funds. In so far as constitutions state, approximately one company out of four contributes a prearranged amount to the funds of its benefit association. Where this is done, the amount of the contribution is frequently a sum equal to that paid as dues by employee members. Other employers contribute an amount equal to 10, 20, 25, or 30 per cent of the members' dues, or an amount not less than 1 per cent of the pay roll. The International Harvester Company agrees to pay \$25,000 into the Association fund each year if the average membership in the Association has been 50 per cent of the total number of employees in the company's manufacturing plants and \$50,000 if the membership has been 75 per cent or more.

There are several ways, often not appearing in the constitutions, by which the company contributes directly or indirectly to the association funds. In a large number of cases, it will be found that the company assumes the cost of the management of the association, at least as far as office space and clerical help are concerned, to say nothing of the amount of benefit work done on company time. The first aid, medical, and nursing departments, where they exist, are closely connected with the examination and follow-up work of the mutual benefit association, but are generally financed by the company. In many plans, since the growth of group insurance, the company pays for the group life insurance, leaving only the sickness and non-occupational accident disability the concerns of the mutual benefit association.

f. Other Sources of Income. The constitutions and experience of mutual benefit associations reveal several other sources of income. Social and athletic activities may be assets or liabilities as far as the treasury is concerned. The yearly dance for the benefit of the association is almost always a great help financially as well as socially. A counter in the company cafeteria or some other convenient location where foods, candy, and cigarettes are on sale often provides a considerable supplement to employees' dues.

4. Sickness and Accident Benefits. *a. Rates per Week.* The total amounts paid by the mutual benefit associations in case of sickness or accident depend on several factors, chief among them the rate paid per day and the number of days for which benefits will be furnished. As with dues, the same rate may apply to all members of the association or different rates may be used for different groups depending on their wages, length of membership, or other considerations. Flat rates average somewhat over \$8 a week. The tables on page 1287 are typical groupings of members in plans where the rates vary with the salary or otherwise.

b. Waiting Period. In practically all plans, the sickness benefits do not begin until after a specified length of time, generally six or seven days. The effect of this is, of course, to eliminate all short illnesses from coverage under the plan and to save the resources of the association for the more serious cases. Many plans, although not all by any means, provide that if a member is ill longer than a given time, as for instance four weeks, benefits shall be paid from the first day of illness. Accident benefits, where paid, generally begin immediately.

THE WESTINGHOUSE AIR BRAKE COMPANY RELIEF DEPARTMENT

Class	Wages or salary per month	Dues (monthly)	Disability benefits per week	Death benefits
I	Under \$35.00	\$0.50	\$ 5.00	\$150.00
II	\$35.00 to \$55.00	0.75	7.50	150.00
III	\$55.00 to \$75.00	1.00	10.00	150.00

D.....	over \$30.00	.30		

c. Length of Time for Which Sickness and Accident Benefits Are Paid. Stated limits are placed on the length of time for which associations will continue payments in case of sickness or accident. Thirteen weeks is the most usual period and next in frequency in the plans studied are twenty-six and fifty-two weeks. The following are typical provisions regarding the period for which payments will be made:

A member in case of sickness or accident which disables such member so that he or she is unable to work shall (subject to the limitations and provisions of these by-laws) be entitled to receive from the Association sick benefits at the rate of \$2 per day, not including Sunday.

No benefits shall be paid for the first week of disability.

No member shall be paid benefits for a total of more than thirteen weeks in any period of twelve succeeding months.

If the board of directors determine that a disability is due to a recurrence or continuance of a chronic disease, ailment, or injury on account of which thirteen weeks' benefit have been already paid, the disabled member shall not be entitled to further benefit on account of disability due to such disease, ailment, or injury.

d. Accident Benefits and Workmen's Compensation. Cases of disability caused by occupational accidents and coming, therefore, under the workmen's compensation laws are treated in one of two ways by mutual benefit associations: Either (1) the association makes no payments in such cases, confining itself entirely to non-occupational accidents or (2) it makes only such payments as will supplement the amount received through workmen's compensation. The first of these possibilities is illustrated by the following provision which is found in a large number of mutual benefit constitutions:

No benefits shall be paid to members or their personal representatives for disability or death for which compensation is provided under the workmen's compensation law of any state.

Payments supplementary to workmen's compensation are provided for in several ways. The mutual benefit association may pay its regular benefits until workmen's compensation payments begin, or it may pay such an amount as, added to the workmen's compensation payments, will equal the usual association payments, or it may pay a smaller amount than in other disability cases.

The Workers' Benefit Fund of the Minneapolis Steel and Machinery Company subtracts the amount of payments made through the workmen's compensation from the amount due by reason of membership in the benefit fund and pays the difference. Although the provisions differ somewhat in different cases, the attempt is to supplement rather than to duplicate compensation payments.

e. Benefits for Employees on Salary. Salaried employees generally receive full pay during disability, at least for a certain length of time. If they receive benefits from the association also, their income during sickness will be greater than their regular pay which will encourage abuse of the disability privilege. Certain companies meet this situation by ruling that such members shall receive no sickness or accident benefits from the association. Their only reason for belonging to the association, apart from a desire to help it to be a

success, would then be the sum paid the beneficiaries in case of member's death.

Another solution of the difficulty is to arrange salary payments and association benefits so that they shall together be equal to the employees' full salary or somewhat less. The company could then consider continuing the full payments after such time as the association payments had stopped.

f. Medical and Hospital Care. Certain mutual benefit associations, in conjunction with medical departments of the employing concerns, are able to furnish members of their medical staff with medical attention and in some cases, with hospitalization if necessary. The Stanocola Medical and Hospital Association of the Standard Oil Company of Louisiana furnishes benefits for its members as follows:

All phases of medical treatment and surgical attention available from the staff of doctors selected by the Association for the members and their dependents.

The Association will also furnish special nurses and hospital facilities to an amount not exceeding \$250 whenever either or both are needed in the judgment of the Association doctor, provided that the hospital treatment and the use of a special nurse for such member or his dependent shall be under the supervision of the Association doctor . . .

The Kimberly-Clark Company Mutual Benefit Association furnishes benefits for its members as follows:

Payments for each working day lost for a period not longer than fifty-two weeks will be made at the following rate:

For sickness or off-duty accident.	\$1.40 per day
For on duty accident—first week.	1.40 per day
Remaining fifty-one weeks.	0.70 per day "

Extraordinary or Operative Benefits

In case of disability classed as due to sickness, should the nature of the illness be extraordinary or necessitate operative measures, or should the case require hospital service to promote recovery, the Association may, upon approval of the medical examiner or the secretary, pay 90 per cent of such bill or bills, providing the member has been in the Association six continuous months or longer and subject to the following conditions

Dental Benefits

Members of the Kimberly-Clark Company Mutual Benefit Association who have been members for six continuous months or longer shall be entitled to *annual* financial assistance on their dental bills to the extent of 50 per cent of such bill or bills provided that such proposed dentistry shall have the approval of the dentist employed by the Kimberly-Clark Company and Neenah Paper Company *before the work is done* . . .

In no case shall the Association be liable for more than \$25 for any member in any calendar year . . .

Optical Benefits

Members of the Kimberly-Clark Company Mutual Benefit Association who have been members for six continuous months, or longer, shall be

entitled to annual financial assistance on their optical bills to the extent of 50 per cent up to a maximum of \$7.50 on any one calendar year.

Proper authorization from one of the medical examiners of the Association must be obtained before incurring any charge under this clause.

g. Mutual Benefit Associations and Health Preservation. Among recent trends in mutual benefit association activity, is that toward increased attention to health preservation. This is due in part to the fact that, with the growth of group insurance, many benefit associations find their work of collecting dues and paying benefits taken over by the insurance company. There still remains much work for the association to do, however, and most logical is that of interesting its members in improving the health experience of the group. This means less illness for individual members and therefore greater production for the company. In addition, it may result in lower insurance rates. The Mutual Aid Association of Eaton, Crane and Pike Company, for instance, carries both death benefits and disability benefits through an insurance company. In addition to the benefits usually offered, this association provides periodic examinations by the Life Extension Institute and daily visits to the home of disabled members by a nurse from the Pittsfield Visiting Nurse Association. It is not, of course, necessary for an association to insure its benefits in order to adopt a program of health improvement. The returns from such a program will be evident both in decreased benefit payments and in lowered insurance rates, if insurance is provided.

5. Follow-up. One of the most difficult problems with which mutual benefit associations have to contend is that of protecting themselves from malingering. If the associations or their employing concerns have medical departments so that a doctor or nurse can investigate cases of sickness, most false claims can be eliminated. This, however, is impossible in a large number of cases. Investigations have to be made by special committees of members and if there is no company physician, a statement from the physician attending the case is accepted. This, of course, leaves many openings for attempts to defraud the association. Until human nature becomes more honest than it is at present, mutual benefit organizations will find it necessary to investigate their claims with all vigilance. However, company nurses or personnel workers, to say nothing of employee committee members, have frequently found that these investigation interviews provide opportunities for genuine helpfulness and for improved personnel relations. If the investigation is made by a doctor or nurse, assistance at the time of crisis can be accompanied by health instruction for the future and both the association and the member be gainers.

6. Death Benefits. Payments to beneficiaries in case of members' death are a part of the plan of most associations. In a few cases, death benefits are the only benefits paid, although this is quite unusual. These payments, when made by the association are generally from \$50 to \$200. In some cases, provision is made, also, for payments of a given sum, as \$50, to a member in case of the death of husband or wife or child.

Death benefits are sometimes paid by assessments levied each time a member dies.

Since the growth of group insurance, death benefits are coming to be handled more usually by this means. The company frequently pays the premiums in these cases, and may insure all of its employees, or members of the mutual benefit association only. The amounts paid in case of death are larger and more likely to be graded according to length of service when paid by the company by means of group insurance than when paid by an association.

7. Administration of the Association. *a. Company Participation in Management.* It is generally accepted by those connected with mutual benefit administration that, as long as the association does not suffer, it is best to have its administration in the hands of employee members as largely as possible. Since, however, a strong hand is often needed in protecting the association against fraudulent claims and undue favoritism to certain departments or members, companies prefer to retain some authority. In some cases, this is accomplished by having an executive secretary who is a company appointee in charge of the association. It is accomplished in other cases by having half or a majority of the association board of directors appointed by the management of the company. In other cases, one or two representatives from management have been felt to be sufficient.

b. The Executive Board. A board of trustees or a board of directors consisting of the officers of the association and representatives elected by various departments is generally the chief controlling body of the association. This body has the final decision on all disputed questions, frequently appoints certain of the administrative officers, and, in general, controls the policies of the association.

c. Officers. Officers are generally elected by the membership and consist of a president, vice president, secretary, treasurer, and other officers as needed. Their duties are those usually pertaining to these offices. Since the secretary and treasurer carry relatively heavy burdens, they are frequently paid a small sum.

d. Committees. The committees appointed or elected to cooperate with the officers and the executive board are those usually found in other associations, except that the visiting committee plays an important role. Where there is no company doctor or nurse, this committee generally has the responsibility of deciding whether or not applications for benefits shall be approved. A certain number of visits to the sick member are often required and the constitution and by-laws provide also, as far as possible, for the submission of proof of disability on the part of the applicant and list conditions under which benefits will not be paid. This committee, however, is often responsible for decisions concerning disability payments, subject to review by the board of trustees.

Questions of Policy. While many questions of detail and policy arise in the consideration of a mutual benefit plan, it is possible to cover but a few in a brief memorandum.¹ Six very usual questions have been selected for discussion to summarize existing opinion concerning such plans.

¹ See *A Manual for Mutual Benefit Associations*, National Industrial Conference Board, 1924, for a very practical, detailed exposition of the program to be followed in inaugurating a mutual benefit association.

1. *Is not the inauguration of a plan an undue extension of employer paternalism?*

Yes, if the great majority of employees have shown the foresight and ability to prepare themselves for the contingencies covered or if a program of education will develop a realization of the importance of such preparedness. No, if wage groups are present in the plant, who are financially unable or psychologically unlikely to prepare for future contingencies. It is less paternalistic to help a man to help himself in the most economical way possible than to allow him to become dependent in time of need upon company or fellow-employee generosity, or the gratuitous services of charitable institutions. If through fraternal or trade union organizations the employee is led to protect himself, by so much a company-fostered plan is unnecessary and paternalistic.

2. *What are the advantages of mutual benefit plans over company financed relief?*

The word *mutual* is highly significant. As long as employees as a group contribute a major portion of the cost of benefits, the plan is an effective agency for education and eventual elimination of any element of paternalism. Contributory plans, while somewhat more troublesome to administer, contain that element of self-respecting responsibility which is truly American. It is easy but expensive to foot all the bill.

It is on the side of *prevention* rather than of *indemnification* or relief of the economic loss due to sickness that company financed plans are most justifiable. The most important trend in company programs for the protection of the wage earner is that toward elimination of accidents, industrial disease, and non-occupational sickness. Few mutual benefit associations are able to finance adequate medical and nursing staffs, however. The company, by assuming the burden of the salaries of doctors and nurses and of hospital overhead, not only improves the quality of the services afforded but is able to place the proper emphasis on the prevention of sickness and on the long-run stabilization of employee effectiveness in a way which employees, even as a group, cannot afford to do. The medical and nursing staff can be used to reinforce and systematize the mutual benefit association's work of financing the employee facing a loss of wages on account of sickness or non-occupational accident.

3. *Why not allow group insurance to cover all risks including sickness as well as accident and death?*

Group sickness insurance, because of higher indemnities, greater moral hazards, inclusive coverage of contingencies, and selling costs, is more expensive. It is less intimate and loses in part the advantages of mutual interest and group feeling as well as that loyalty toward and respect for fellow employees which reduces the willingness to malingering or to feign illness at the expense of the group. Death, however, is not only a sharply defined contingency which is seldom self-encouraged but which must be indemnified by a much larger sum to provide for surviving dependents. The lessened intimacy and higher cost of commercial insurance must be considered secondary to absolute certainty and ample indemnification in considering the best means of meeting this need. Further, actuarially, life (and accident) insurance has reached a

much greater degree of exactitude than sickness insurance. In the latter field, the mutual benefit association can perhaps adjust itself more economically to the needs of the local situation in arriving at proper rates as well as in protecting itself against unfair claims. The advice of an actuary is of greatest importance in determining rates and benefits, where insurance is not used.

4. *Can a small company safely inaugurate a mutual benefit association without reinsurance?*

No, except at the risk of assessments which may end the life of the association at the time it is most needed. To be able to withstand a drain due to an epidemic, the membership of the association must be sufficiently large to spread the risk over a group of marked diversity. The insurance principle does not properly apply until an averaging of risks takes place. The employees of a small company are too limited in number for proper averaging of the incidence of normal sickness and even a large company may well reinsure if residential concentration of employees makes epidemics more likely.

5. *Should the reserve plan or the assessment plan be followed?*

The reserve plan, in which dues are sufficiently high to meet all contingencies, is safest, easiest to administer, and less likely to arouse dissatisfaction once wide membership is secured. The assessment plan, while possessing the advantage of apparent economy at the moment, is more likely to cause fluctuating membership and delay in meeting obligations. A combination of the two methods is, perhaps, best. Excessive reserves are unfair to non-beneficiary members leaving the company's employ and high dues discourage wide membership in a new plan. Lower dues and infrequent assessments in times of heavy drain may be most satisfactory to all concerned.

6. *Is a mutual benefit plan to be managed by the employees?*

In most companies there are few employees possessing that combination of ability, sustained interest, and breadth of contact among their fellow employees which is necessary if they are to administer a plan without company assistance. Those possessing these qualifications are likely to be of the supervisory or office staff. It is better to recognize the management's interest in the plan directly than await the drift toward the election of management representatives by the workers after unfavorable experience with association officers elected from the rank and file alone. The company must become, directly or indirectly, an influence toward fairness, efficiency, and conservatism. It must emphasize the importance of actuarial advice. Further, in most plans use is made of the facilities of the company office in the collection, management, and disbursement of association funds. Even if no additional contribution is made by the company, the provision of these facilities warrants some company representation in the administration of the association. While every effort should be made to develop active and responsible officers elected from the rank and file, the importance of safeguarding employees' investment in the association and the dissatisfaction resulting from possible favoritism, inefficiency, or failure to meet obligations promptly does not allow company officers to be too diffident in assuming some responsibility for the proper management of association affairs. The extent of the assumption of responsibility may vary from the appointment of a large representation on the executive board of the association, including

the appointment of a treasurer, to occasional conferences with the employee officers of the association in order to review and discuss any problems which have developed. The assurance of careful and frequent auditing of books is most certainly a proper company function.

ACCIDENT PREVENTION

BY ARTHUR H. YOUNG, *Secretary, Industrial Relations Counselors, Inc.*

Safety work originated in the attempts of certain individual employers to reduce the terrific human waste of accidents, and has been stimulated by workmen's compensation legislation. It is now generally agreed that accident prevention efforts will be productive of the best results if they are planned to include:

1. Organization, through which the general policies of an industry or company, with respect to the problem, are administered and executed.

2. Supervision, through which the supervisors are advised as to accident hazards; through which procedure is prescribed for education as to unsafe practices; and through which rules and regulations are enforced.

3. Education, through which rank and file employees are instructed as to occupational hazards and the safe methods of performing their everyday work.

4. Engineering, through which the structural and mechanical conditions are made safe, *i.e.*, the material conditions under which work is done are put in safe physical condition and are so maintained.

5. Statistics, through which the specific problems requiring solution are indicated and by which the progress of accident prevention efforts is gaged.

Organization. The organization for safety work necessarily varies and depends largely on the industry, the relationship of individual companies within an industry with respect to problems of mutual concern, and the size of any given company.

Accident prevention work largely concerns the individual, his state of mind, his understanding of occupational hazards and his disposition to comply with, or disregard, rules and regulations for safety as promulgated. Safety work, therefore, requires an organization within the company on a basis that will insure full observation of employees in their everyday work and the dissemination of safety propaganda through every possible medium. The employment of a safety engineer and the organization of committees, including a central safety committee, and supervisors' or workmen's safety committees, are considered as essential to a well-organized, practical safety effort.

The duties of the *safety engineer* may be summarized as follows: to have general supervision of the safety work in all departments; make frequent inspections of physical operations; counsel with local committees; see that approved recommendations are carried out; investigate accidents; fix responsibility for accidents and make recommendations to prevent the possible recurrence of similar accidents; keep statistics of accident and labor data and make therefrom monthly and special reports to heads of departments and

other officials; supervise and conduct the educational work through safety committees.

The number of committees and their use will in part depend on the size of the organization.

The central safety committee may be composed of the manager or general superintendent as chairman and four or five other men occupying responsible positions.

This committee should meet once a month and have general supervision over all accident prevention work. Specifically, the committee should give consideration to and act upon safety work as follows:

1. Direct the expenditure of all funds appropriated for safety and sanitation.
2. Establish standards or indicate standards to be followed for all mechanical guarding and construction work.
3. Review reports and recommendations of safety specialists, and foremen's or workmen's safety committees.
4. Supervise safety inspection work.
5. Outline educational methods and direct safety campaigns.
6. Prepare statistics of accident experience divided as to cause of accidents, accident frequency and severity rates, cost, etc.

Local or departmental safety committees may be composed of workmen or workmen and supervisors jointly. Rotation of membership by periodic changes in personnel may be provided for. These committees should meet regularly once or twice each month. Their duties should include:

1. A review of accidents occurring since the last meeting and fixing of specific responsibility.
2. Inspection of department and recommendations to eliminate unsafe conditions or practices.
3. Consideration of the report of each committeeman on his personal activity in safety work.
4. Investigation of and report on all serious accidents immediately after occurrence.
5. Cooperation in the preparation of safety rules and regulations.

Supervision. Experience has indicated that success in accident prevention work is attained in proportion to the degree to which supervisors recognize that safety work is, in its final analysis, an operating problem and as such, demands their interest and wholehearted cooperation. Supervisors should therefore be held strictly responsible for the accidents to men under their supervision.

Supervisors should be constantly on the alert to note unsafe conditions and practices and to have them corrected; to investigate fully and report on accidents to their men; to instruct employees as to occupational hazards; and to enforce rules and regulations as published. To this end frequent meetings of supervisors should be held to discuss the problems and assist in developing preventive measures.

Education. The experience of industrial plants in accident prevention work has clearly indicated the necessity of inculcating habits of caution in

rank and file employees. Educational activities generally carried on under the direction of the safety engineer are:

1. Installation and maintenance of safety bulletin boards.
2. Safety meetings of employees at convenient recess periods or on paid time.
3. Intersectional and interdepartmental safety contests.
4. Formulation of safety rules and regulations and distribution to employees as rule books.
5. Arrangement for safety meetings of superintendents and the foremen.

It is generally agreed that the basic problem of accident prevention is to change the naturally careless attitude of persons to a careful one. This result can be best attained by persistent education.

Engineering. It is essential that all drawings or blueprints before leaving the drafting room be checked for safety against the safety codes or standards adopted for the company. Space should be provided in the title of the drawings for the initials of the person checking this item. Specifications for the purchase of all equipment should include a clause to the effect that gears, chains and sprockets, and other dangerous moving parts should be effectively guarded.

The safe practice leaflets of the National Safety Council may be used as a guide in developing standards best suited to the individual requirements of the company. If the organization is a large one with scattered plants it would be well to have the chairmen of the plant central safety committees meet quarterly or semiannually as a standards committee, for the purpose of developing company standards and practice.

Statistics. A uniform system of collecting and tabulating accident statistics is indispensable to a proper understanding of the accident problem and the effective prosecution of safety work. Such a system includes accident record books covering all details of the accident, the supervisor's report on individual accidents, and periodic reports showing accident frequency and severity rates, cause classification, and cost.

Plant Accident Record Book. At each plant of the company basic accident data should be entered by principal departments in an accident record book with columns for the personal history of the injured employee; details of the accident as to time, place, cause, nature of injury, and other circumstances; number of days lost; accident costs divided into compensation payments, surgical expense, etc. A suggested form incorporating the above essential data is given (see Fig. 1).

Report of Accident. As soon as a foreman is notified of an accident, he should investigate, make a report, and send it through regular channels to the department head, a copy being sent at once to the safety engineer.

Report of Accident Frequency and Severity Rates. From the basic data entered in the accident record book, a monthly tabulation should be prepared giving departmental accident frequency and severity rates. The accident frequency rate should be expressed as the number of lost-time accidents per 1,000,000 hours worked. The accident severity rate should be expressed as the number of days lost per 1,000 hours worked.

THE _____ COMPANY
ACCIDENT RECORD
_____ PLANT

[illegible]

Fig. 1.

A similar annual report should be prepared and be supplemented with a tabulation giving accident costs by departments, by plants, and for the company as a whole, dividing the costs into compensation payments and surgical expense.

Cause Classification. The classification of accidents by cause is of utmost importance as it directs attention to plant conditions or practices which require correction. Such a general tabulation should be prepared at least once a year, and more frequently in the case of special hazards.

UNEMPLOYMENT BENEFIT AND EMPLOYMENT GUARANTEE PLANS¹

BY BRYCE M. STEWART, *Industrial Relations Counselors, Inc.*

Only comparatively recently has it been recognized that unemployment is not chiefly due to personal causes but is related to the disorganized state of the labor market and the irregularity of business operation. Cyclical fluctuations are thought to constitute the principal obstacles to the maintenance of prosperity and, with changes in industrial methods and organization, comprise the principal causes of unemployment. This suggests that the chief point of attack is the cycle but also encourages the development of statistics of unemployment, of public works, vocational guidance, and public employment offices by state and national governments. Individual employers are urged to conduct their business in such a way as to minimize seasonal irregularity and the effect of the business cycle. But it is clear that no amount of effort along any or all of these lines will entirely do away with unemployment. Compulsory unemployment insurance has been adopted by many European governments to deal with the problem as an expected occurrence rather than as an emergency.

In the United States certain unions and employers, both separately and jointly, have undertaken to be responsible for the unemployed in their organizations under formal plans. Development of voluntary unemployment benefit plans in the United States has, however, been so meager and experience for the most part so brief, that it is impossible to lay down any general rules for instituting and maintaining such schemes. The thirteen benefit plans operated by companies alone prior to 1930, and the twenty-four plans operated by joint agreement between companies and trade unions, as well as the more numerous union plans, do, however, suggest certain considerations which must be kept in mind by anyone devising a formal plan for the payment of unemployment benefits or for the guarantee of employment.

1. In planning the structure of the benefit schemes, choice has thus far been made between *the guarantee of employment and the benefit types*, considering as guarantee plans only those that guarantee full wages for the period specified. The benefit type is the more prevalent. It is less in the nature

¹ This section is taken from B. M. Stewart, "Unemployment Benefits in the United States," Chap. VIII in collaboration with M. L. Stecker, J. C. Barber, and M. B. Gilson, Industrial Relations Counselors, Inc., 1930.

of a promise of full-time employment, something beyond the power of any management, amid the breaking down of trades by inventions and the shifting conditions of modern industry. There is a record of one company in which there has been a change from the guarantee to the benefit form, but so far as is known there has never been a change in the opposite direction.

2. If it is proposed to give *protection against all risks of unemployment*—seasonal, cyclical, and emergency—ideal procedure requires that the extent of each be separately calculated and that the funds collected for compensation of unemployment be established so as to take all three into account. If this is not done, any monies accumulated while only seasonal slackness is being experienced, for example, may come to be regarded as surplus and the reduction in contributions or increase in benefits which may result in the end will mean that when the other risks require benefit payments the money to meet this need will not be available. No calculation of the risks of unemployment is adequate which does not cover the complete cycle and is certain to be erroneous otherwise unless adjustments are made which take into account the position of the cycle when the plan is started.

3. In setting up a plan of unemployment benefits, consideration should be given to the *establishment of a dismissal wage* as an integral part of the scheme, a type of provision adopted by a number of prominent firms including some with unemployment benefit plans. A dismissal wage would serve to deter the management from increasing the force unnecessarily; the employee released would be aided during his search for other employment or an old worker might be tided over the period until he could claim a pension, he would be compensated in some degree for reduced wages on a new job. In any such scheme of compensating unemployment due to permanent release, the question should be considered whether or not an employee who has exhausted his right to benefit for other kinds of unemployment should be able to resign and receive his dismissal wage.

4. For measuring the different risks of unemployment and for the direction of preventive effort, *statistical records* are obviously necessary. The data of chief importance for this purpose are the total man hours of employment in each pay period and the hours of voluntary absence without pay. The difference between the sum of these two and the total full-time man hours in the pay period will give the man hours of unemployment. If collected for a sufficiently long period these data will indicate not only the average annual periods of seasonal unemployment, but will have covered cyclical and emergency unemployment as well and will permit the best possible estimate of the financial provision necessary.

At the beginning of the operation of a plan, in most cases, estimates must be substituted for statistical experience and it is necessary to take care to make them conservative, looking to their revision as experience indicates. A majority of existing benefit plans underestimated their unemployment hazard.

5. Whether there is a true actuarial basis for an unemployment benefit plan or not, the probable amount of the *monies that will be available* for financing the scheme must be determined. It is important that the financing be related to a definite and fairly constant base such as the pay roll, rather than to a more uncertain quantity such as profits. If a percentage of the

pay roll is to be set aside, the amount of the annual disbursement of wages averaged over the entire business cycle is the best indication of the basic sum upon which contributions should be assessed, and the percentage will be fixed to yield the amount set. The scale and duration of benefit and conditions under which it will be paid will then be adjusted to hold the demands upon the funds within the predetermined totals. Establishing a maximum annual benefit allowed any employee will afford an additional safeguard to the solvency of the funds.

6. Whether or not the *employees are to contribute* must be considered. While the trend in the plans set up by joint agreement seems to be toward placing the entire burden upon the employers, the decision ultimately rests on such considerations as the amount required to give adequate protection; the financial ability of the management to make the whole provision and certain factors of managerial policy; the employees' ability to pay, their attitude toward participation and the extent of their control of the market; and the relative effects of contribution or non-contribution on malingering.

7. When, as in most cases, the funds available at the outset permit a very *limited degree of protection*, the choice inevitably arises between attempting to cover all unemployment in a small way or of eliminating certain forms of unemployment and paying higher benefits for the others. Short time, or time lost through shut-downs or permanent release may be excluded from benefit, for instance. This device is open to the objection that unless the nature of the business makes it impracticable, the management to a certain extent has the power of forcing the unemployment into a non-compensatable form, while the employees are likely on their part to insist that they be permitted to take their lost time in a form that is compensated under the plan.

8. *Further limitation of protection* may result through the fixing of conservative length-of-service requirements and waiting periods for participation. While these are necessary administrative devices, their use for the purpose of cost control may be questioned on the basis that it is generally better to defer the payment of benefit until a sufficient fund has been accumulated to permit liberal provision than to hedge the scheme about with regulations that confuse the employees and restrict the protection so materially that their interest and confidence are not secured.

9. Another question relates to whether the *benefits shall be a flat sum equal for all employees or a percentage* of each employee's full-time earnings. If the employees contribute in proportion to earnings, the flat-sum method introduces discrimination, in that, on the principle of need, higher benefits per dollar of contribution are granted to the lower wage groups than to the better paid employees. If the management bears the whole expense and provides flat-sum benefits, the principle of need is still recognized. While those in the higher wage groups might adopt the attitude of some under the union plans, that the benefit is a dole to be given only those in distress, it is possible that the higher wage groups might consider themselves unfairly treated in that they would be receiving less in proportion to the market value of their services than those on lower wage rates. They might even adopt the view that the management would do better to abandon the plan entirely and pay the benefit as wages. It is noteworthy that the largest existing joint plan, and all but

one of the company plans, have adopted the principle of paying benefit in proportion to the loss in wages.

10. When a joint or company plan covers more than one establishment of sufficient size to permit a *separate fund* for each, a decision is necessary as to whether company funds shall be set up or whether the contributions on account of *all the units shall be pooled*. In the limited experience of one of the large joint plans which pooled all contributions, the bulk of the disbursement for benefits went to workers in shops that had afforded only a small volume of employment, while the employees of shops where work was more plentiful who, on a percentage of pay roll basis, had contributed most to the fund, received much less. The inequity of this situation was accentuated by the fact that the plan excluded from compensation a considerable period of seasonal unemployment, and as the seasonal slackness of some of the firms with more regular employment at times did not exceed this uncompensated period, their employees received no benefits at all. In so far as the greatest irregularity of employment was confined to identical firms season after season either because of their inefficient management or concentration of production on lines of greatest seasonality, the same shop groups of employees continued to receive the lion's share of the benefits and, conversely, the employees of units with more regular work continued to participate only in a small way or received no benefits at all. Moreover, under this procedure the necessary "squeezing-out" of employees from marginal firms and the absorption of the latter's business by more efficient managements was retarded, and the incentive to regularization of employment was weakened.

11. Confidence and goodwill are indispensable for the success of any benefit scheme. To secure these in full measure requires that the *funds shall be segregated* from the monies of the business or organization and vested in trustees with power to use them only for the purposes indicated, for their investment in conservative securities and with instructions for their equitable distribution if the plan should be terminated.

12. Unemployment benefits are likely to prove costly. The probable high costs make it especially important that the plan should be placed on an actuarial basis as soon as possible, but that leaves the scheme in danger at the outset. To provide against this, payment of benefits should not be commenced until a *substantial reserve* has been accumulated and initiation of benefit outlay should be timed with the uptrend of the business cycle so far as careful planning will permit. The limited voluntary experience with unemployment benefit plans in the United States and the large governmental systems in Europe record many instances of forced deliberalization of the terms through encountering a depression before a sufficient reserve had been built up. A long period of accumulation at the outset is more feasible, of course, when the employees do not contribute and hence are not in a position to demand immediate benefit. As said earlier, the scale and duration of benefit and the maximum annual amount of benefit allowed should be determined on a conservative basis and, if possible, their actual terms should not be announced until the end of the initial period agreed upon for the accumulation of funds, so that they may be fixed in the light of the experience of the period.

13. Integration of the unemployment benefit plan with a scheme of *employment regularization* and a broad industrial relations program should make possible a minimum of unemployment benefit expenditures. Some farsighted firms have attempted to regularize their employment before adopting unemployment compensation. If training is provided and encouragement given to employees to become efficient on more than one operation so that surplus workers in one department may be transferred to expanding sections, and if there is an employment department with complete knowledge of the entire labor demand and supply of the business, with facilities for transfer between plants of the organization in the same and other localities, much in the way of stabilization may be accomplished.

14. It is probable that some state governments will experiment with schemes of *compulsory unemployment insurance*, and promoters of industrial plans should have regard to this consideration in formulating their schemes.

Appendix

At the end of 1929 there were eleven unemployment benefit plans operated by companies, twenty-two under the joint control of unions and employers, thirty-seven instituted by local unions, and four covering entire union jurisdictions. The structure of the plans showed considerable diversity as between the three groups and also within each group. Five sets of provisions made up the structural scheme: eligibility requirements, definition of unemployment, source of income, scale and conditions of benefit, and administrative regulations. The variety in the provisions and their application resulted from the different needs and conditions of the organizations and industries covered and the different factors affecting the adoption and development of the schemes.

All three groups of plans have required a probationary period of membership in the union or service with the company for a workman to qualify for participation. While unemployment was generally defined as involuntary idleness due to lack of work, most of the plans provided that such unemployment in certain of its phases shall not be covered. Income was derived solely from the members in the union plans, from the employers and employees or from the employers alone in the joint schemes, while the company systems were financed entirely by the managements. The benefit provisions indicated the scale and duration of benefit, the waiting period before unemployment was regarded as compensatable, any other period for which benefits would not be paid, and usually the maximum amount that any worker might receive in the year.

During the depression of 1930 and 1931 three more company plans became operative and each incorporated original and interesting features. The principle of employee contributions, heretofore limited to certain joint agreement plans, was introduced in one of the schemes which covered the employees in all branches of a large corporation. The fund accumulated for six months before payments began. The second plan applied to the workers of five small firms in a Middle Western town and provided for shifting employees from company to company, with benefits paid from the individual company funds.

The latest of the schemes to be announced carried this cooperative policy even further. Fourteen companies employing about one-half the wage earners of an eastern industrial city, each agreed to put into effect a plan for

the payment of unemployment benefits. Reserves were to be built up by the individual companies during 1931 and 1932, and benefits to begin in 1933. Contributions may be required from employees at any time that payments become so heavy as to endanger the solvency of the funds, but in this event company contributions will be correspondingly increased. Each employee who is laid off must register at the city central employment bureau which these companies were instrumental in establishing, and to which they report all vacancies.

PSYCHOLOGICAL FACTORS OF OBSOLESCENCE OF WORKERS IN MIDDLE AGE

BY ELLIOTT DUNLAP SMITH, *Professor of Industrial Engineering, Yale University*

The advance of medical science is making the expectancy of life of the worker longer and longer. The advance of engineering and managerial science, however, seems in some quarters at least, to be making his expectancy of working life shorter and shorter. The fact that the advance of engineering service has simultaneously brought about the transfer of much of the heavy physical work from the worker to the machine, pointedly suggests that such difficulty as there is, is psychological, not physiological—that modern industry is making increased psychological demands which the worker after middle age is no longer able to meet.

Effect of Advancing Years. There is no question that psychologically, as well as physiologically, advancing age does ultimately bring about deterioration. The decline of physical strength and vigor in old age in itself impedes the power of mental application. In addition, the senses and even the thinking processes ultimately become directly impaired. Eyesight and hearing fail, memory wanes, and often even the reason loses its brilliancy and power. Above all, learning power seems to fail, for the old adage that "you can't teach your grandmother to suck eggs" can, in old age, be justified as fully upon the incapacity of the grandmother to learn as of the grandchild to teach her what she does not know. Such changes, however, are rarely extensive until ripe old age. Yet today the problem of superannuation that is attracting most attention is superannuation shortly after middle age, when until recently, a man was supposed to be at the height of his mental powers. It is possible, however, that coming declines cast their shadows before; and there is in middle age a less conspicuous loss of mental power, which while unobserved and immaterial in the looser industrial conditions of the preceding generation, is of serious consequence in meeting the more exacting industrial demands of today.

Psychological studies of the effect of advancing years unfortunately have been few. Moreover, much of the experimentation has been haphazard, and is rendered unreliable because of the difficulty of separating the effect of age from that of other influences. Adult human beings are especially difficult to study. On the one hand, the normal environment of adults is so complex in our modern civilization that it is all but impossible to segregate the influence

of individual forces. On the other hand, it is almost impossible to carry on with adult persons, for any considerable period of time, experiments in which the entire environment is artificially so controlled as to confine its influence to determinable factors. Still, some careful psychological studies have been made and these almost uniformly indicate that the body feels the weight of years before the mind and that the mental changes brought about in adults by the mere process of advancing age—at least until they are well on in truly old age—are few and insignificant.

The most careful work I know is that of Hollingworth and of Thorndike.¹ Thorndike, in 1928, in addition to reporting his own studies, carefully reviewed all previous experiments. Both men agree that age causes a very slight decline in the sensory equipment, which may start even in the early thirties. They also agree that while there is no appreciable decline in intelligence, there is evidence of some slight impairment of other mental processes such as memory and learning power. The average adult, according to Thorndike, reaches the peak in *measurable* learning power at twenty-five years of age, and by forty-five has suffered a decline of appreciable consequence.² Both agree, however, that such loss as they can discover in measurable learning capacity is not the result of the mere passage of years, but is almost wholly due to extraneous factors.

Importance of Factors Other Than Age. Among the factors other than age which tend to bring about a decline in learning power in the average adult as he grows older are two of outstanding importance: the atrophy of acquired learning habits consequent upon disuse, and the amount of unlearning involved in new learning after old and inconsistent habits have become well set. The effect of these forces is illustrated by Thorndike's studies of the influence of age upon the learning power in middle age of convicts and of college men. Compared to convicts, college men decline more in learning power as they grow older, and yet their greatest decline in learning power is in fields in which they have never done any studying in college. Apparently, since the students do more learning throughout youth than convicts, by twenty-five their inherent learning ability is more amplified by habits. In later years when these habits of skilful learning fall into disuse and atrophy the college man suffers a relatively greater decline in learning ability than the convict. On the other hand, when the college man undertakes, in middle age, to learn in an entirely new field, the difficulty of overcoming then the mass of inconsistent habits which he had established in college by extensive exercise in learning along other lines, is greater than the difficulty of reawakening and utilizing learning habits impaired by disuse.³

In every instance such decline in learning power as is at all reliably established seems to be due primarily to influences other than merely growing

¹ See HOLLINGWORTH, H. L., "Mental Growth & Decline," Appleton, 1927.

THORNDIKE, E. L., and others, "Adult Learning," The Macmillan Company, 1928.

² Such learning power as can be measured is of necessity confined to limited and generally fragmentary types of learning and to artificial conditions of measurement. This renders any report of mere measurement of learning power an incomplete record.

³ This explanation is mine. Thorndike makes no explanation of the fact that students decline most in learning power in fields in which they have done no previous studying.

old. The testimony of such psychological evidence as we have is, as Thorndike says, that while there is some observable decline, "the decline is not only small in amount: it is also probably in part avoidable by the simple expedient of continuing to learn," and that until true senility, "if other factors are equalized, the influence of age upon learning ability approaches zero." Judging from these psychological studies, the major psychological problems of increasing years are not due to mental deterioration—but to obsolescence. For there is nothing inherent in middle age that renders workers psychologically unfit—if they cannot be successfully used in industry it must be that their acquired mental equipment is inadequate and out of date and that the task of replacement is beyond their powers.

The fact that it is generally believed that middle aged people usually learn less than younger people is not inconsistent with these psychological findings. In the first place, as every teacher knows, the amount a person actually learns is not a measure of how much he is capable of learning. In middle age there is less that it is necessary to learn, for middle aged people have in earlier years learned enough to meet their social demands and to earn their living in established ways. Their days are well filled doing things they long ago learned to do. To start out into some new field without guidance is baffling to an adult just as it is to a youth. To go further in a field where one has already gone far, brings one sharply up against the law of diminishing returns. Each additional increment of learning is harder won as one gets further and further from the simple underlying generalities. Each additional increment seems smaller and less worth the effort in proportion to the learning already done. And usually, because of the constantly increasing magnitude, subtlety, and confusing interpenetration of principles that occur as one goes further from the elementary outline of a subject, each additional increment of learning requires a greater degree of intelligence to master. Hence, the general observation that people learn less in middle age, while probably an accurate observation of how much they learn, is not indicative of any decline in learning ability.

The Testimony of Experience. The testimony of practical experience, moreover, confirms the evidence of psychological experiment, that such changes as occur in middle age are the result of experience and not changes inherent in becoming older. People who have been constantly engaged in creative work lose little originality with the passing years. Witness the number of men, from John Dewey to Alfred Whitehead, who do creative writing of the highest order long after they have passed middle age. Witness also the continued inventive genius of such men as Edison and Steinmetz. Nor is this true only of great men. For example, the most creative work room supervisor I have ever had—a man who evolved new ideas and methods constantly—was well past sixty; while in one of the most progressive New England companies the head of the new goods department is a man over seventy.

It is capacity to perform more than capacity to create, however, that is vital to the average employee in industry. Here also the evidence of practical experience parallels that from the psychological laboratory. In practically all trades and professions, where the fundamental requirements have remained

the same and the process of learning and of developing ability through practice have therefore been continuous, workers rarely reach their peak until the thirties, and continue to command their highest wages or salaries throughout middle age. This is true of tradesmen such as machinists, carpenters, guillotine cutters, or jewelry case makers, as well as executives and engineers. It is even true to an astonishing extent on jobs where because of the simplicity of the operation, the value of accumulated skill and trade knowledge is apparently small. In my own observation, for example, even on so simple a process as the hand shear or the foot punch, where the worker merely brings down a shear knife or punch head upon a piece of paper registered against a gage, workers with fifteen to fifty years of service generally outdistance their younger coworkers. For where learning is continuous, even when thorough mastery can be early attained, the acquisition of trade knowledge and the formation and improvement of more and more effective habits of skill usually more than compensate for any possible loss in nimbleness or inherent learning capacity.

Human Nature Adjusts to Gradual Continuous Change. It is by no means necessary that the job continue unchanged year after year for the employee to increase in skill as he grows older. Even in the face of striking developments, provided they are accomplished without sudden spurts, the power of habit to improve what is done repeatedly, continues to bring its return. For under the guidance of constantly progressive management the skill which is thus evolved can be molded as it develops so as to conform to improved conditions, methods, and standards. Human nature can adjust to great changes provided the process of change is gradual. Certainly, few jobs have changed more under the constant criticism and stimulation of scientific management than those of the salesman and the executive. Yet in those concerns where the development has been continuous and the salesman or executive continuously exposed to the process of development, middle-aged people still hold the principal positions. Similarly, in factories which have made outstanding but continuous developments in manual or clerical methods, middle aged employees hold their own.

The situation is entirely different however, when, because development of methods is sporadic and involves abrupt changes, the employee is faced with the problem of making fundamental changes in a brief time. The difficulty of learning is always greatly multiplied when learning can not proceed one step at a time, but must cover in a single leap what should have been covered in many steps. Moreover, except in some such industry as the automobile industry, where the newness of the product offers an unworked opportunity for engineering and managerial development, abrupt revolutionary changes usually occur only after a period of stagnation. It is in backward industries or companies, just as in backward countries, that revolutions take place. For during a long period of stagnation, neglected opportunities for progress accumulate and make drastic change possible, and indeed, necessary if the concern is to survive. Concerns that are constantly and scientifically striving to seize every opportunity for development, discover their opportunities in such early stages that changes which would have been drastic if delayed, are gradually brought about in small increments.

Serious Effects from Stagnation. The psychological effect of stagnation upon the employee, followed by drastic change, is doubly hard. During a period of stagnation, because no job learning is done, the habits involved in job learning just as with student learning gradually weaken. Learning becomes an unaccustomed and baffling effort. At the same time the obsolete working habits become strongly entrenched. If habitual methods are repeated without change year after year, they acquire a strong hold. The mind, and even the body, adapts itself to such repeated activity. For instance, I have even seen the hand of a case nailer, who year after year held his nails in exactly the same way eight hours a day, become so bound in this position by muscular and skin growths that it took a serious operation to enable his hand to be opened out to a normal position, and even then it could not be restored to normal usefulness. And so with mental growth; with exact repetition, habits become set, and even those which are superficial in substance become strongly ingrained into the person. Thus, for example, mannerisms become indelibly set if allowed to continue unaltered, and similarly "mannerisms of thought" and, even more, the fundamental articulations which underlie working skill, get an unconscious but tenacious hold.

Unchanged habits, moreover, not only grow strong with exercise, but as they grow strong cease to require conscious control, and then gradually withdraw from consciousness altogether. For this reason a skilled worker is often a poor teacher. He does not know, and in fact often cannot discover, just what are the particular motions and acts in which his skill resides. The habits which control the subtle articulations which underlie skill, because they are deep set and fundamental, retire particularly far beyond the reach of conscious attention. All this makes sudden unlearning additionally difficult. It is hard enough to unlearn processes of which we are conscious, but to seek to discover and uproot subtle habits long since hidden from conscious thought is to face multiplied difficulty. Anyone who has long followed one practice in his favorite sport and then shifts to another can understand this from his own experience. If a man who has swum breast stroke undertakes to swim the crawl he finds the task all but impossible. He doesn't seem built for it. Ways of working his muscles and timing his motions that he can no longer bring into consciousness are inconsistent with the new stroke. Superficial conformity is easy, but to make those fundamental but subtle articulations which make the stroke effective is an all but hopeless task.

Similarly, when a period of stagnation is followed by rapid change—the long-service worker is both confronted with a task of rapid learning and a far more difficult task of unlearning. But, unfortunately, this is not all. The thinking of the employee about his work has been subject to the same stagnating influences as his work itself. He has been so used to thinking about it as the right way, that he has grown to accept its rightness as axiomatic. He no longer sees possibilities for improvement, or entertains ideas which suggest that better ways exist. Hence, change following a period of stagnation is not only difficult, but to the employee it seems both unwise and unnecessary. Faced with these handicaps the middle-aged, or rather the long-service worker, is unable to adjust.

For example, the most valued workers in a department of about 140 jewelry box makers and liners, with which I was long in contact, were a group of about thirty employees who had been with the company over a quarter of a century. The quality of their work was one of the company's cherished assets, and their earnings on piece rates were the highest in the department. Not only this, but the work they did was of such a difficult nature, and the difference between their proficiency and that of a new worker, especially during the first year, was so discouragingly great that few young people were willing to stay long enough to become proficient. A few years later, however, the department, which had followed the same methods for decades, was thoroughly reorganized and striking changes in product and method rapidly introduced, including the substitution of highly subdivided methods of mass production for the former craftsmanship method under which a single employee made a complete box. As a result, these same employees became one of the department's most serious problems because of their inability, after years of gaining remarkable proficiency in antiquated methods, to adapt themselves to products and processes of a fundamentally different sort.

This inability to adjust to sudden change following a long period without change is as true of managerial as of manual or clerical employees. Again and again, where departments or factories have been allowed to stagnate, I have known even fairly youthful executives to be unable to adapt themselves to the reorganization that followed. In the face of such conditions, the only advantage of the younger executive or employee is that his learning capacity has been more recently exercised and that he has less to unlearn.

When one sees, as I have seen, an executive of thirty-five who has been more than twenty-one years in one department that was still operating "in the good old way," come up against the problem of adapting himself to a reorganization, one can clearly visualize the process by which mental obsolescence occurs. The individual has been brought by his work into a condition of conformity to antiquated and largely unconscious methods of thought and action so deeply set as vigorously to resist change. He has been afforded by his work so little necessity or opportunity of change or development that he has forgotten how to learn. Then the methods which he has learned too well have been suddenly discarded and he is faced with the necessity of promptly losing the grip of the old and acquiring the new. The fact that he is unable to do so is not due to his age but to the fact that for year after year he has been forced to remain in a rut.

Effects of Age on Personality. An individual's value in industry and his willingness, if not his ability to learn, of course, are affected by his temperament as well as his intellectual qualities, which, like the factors of intellectual ability, are commonly believed to change with age. In general, people past middle age compared to people in their twenties are thought to have among other personality differences, less enthusiasm and willingness to expend energy lavishly, but more patience and persistence; less willingness to take risks or make changes, but more poise and stability. But just how far this is an inherent result of age, or even how far these changes occur at all is a difficult problem to determine. Personality qualities are so intangible that they have not yet been reduced to sufficiently determinable values to

permit accurate experimental measurement. Moreover, in such a subtle field general observation is especially unreliable and likely to be colored by the circumstances, background, and point of view of the observer. Thus the opinion of executives as to the effect of middle age on the personality varies widely, largely depending upon what their personal experience with younger and older workers has been, and sometimes apparently upon the age group in which they find themselves. Executives are even more divided on the value of the changes middle age brings than upon what these changes are. For so much of the value of personality qualities depend on the situation in which the person finds himself, and even more upon his possessing personality characteristics which interweave with each other and with his intellectual qualities to make a well-balanced whole. Poise, for example, may become a limiting emotional inertness if united with other conservative factors, while willingness to take risks, as has recently been amply demonstrated, can cause untold losses unless united with a proportionate capacity to take risks wisely and applied in a situation in which risk taking is a desirable practice.

The same influences of habit that modify learning ability moreover affect personality. For example, if a person has been sheltered by his work and life from change, he will become increasingly cautious and timid, while, if he has been constantly exposed to risk he is likely to exemplify the maxim "the older the bolder." Besides the effect of his work and life upon his personality is likely to be collateral to their effect upon his intellectual equipment. Thus, if he has made constant progress throughout life, his long practice in the hard work of developing new skill will increase not only his habits of skillful learning, but also his patience and perseverance in learning, and his attitude toward new measures. If, by experience in making decisions and observing consequences, he develops the habits which underlie penetrating judgment, and accumulates a wide background of experience on which sound judgment can be based, this will give value to such perseverance as well as to such willingness to take risks as he may have. If on the contrary he has worked long on a single job, he will not fully develop the conservative sides of his personality but his conservatism will be reinforced by the exceptional difficulties of unlearning as well as learning, and by the intellectual bias that will make change seem unwise. Moreover, his long investment of skill in a single type of performance will, as a matter of fact, make his loss serious if he scraps or is forced to scrap all his accumulated trade knowledge and ability in one direction to start up from the bottom in another. Because of the effects upon his mind and character of his past experience his desire to avoid change is not without practical foundation.

Source of Difficulty within Industry Not in Human Nature. Thus the problem of the inability of middle aged people to meet the demands of present-day industry is not primarily due to the psychological effects of advancing years. Practical experience confirms the results of the psychological laboratory that the principal effect of the passing years is that they provide inescapable exposure to the influences of what a man does and experiences as the years pass. The power of man to continue to acquire and to develop habits gives to increasing years the opportunity to offset any slight decline in faculties or change in temperament which might occur, by increasing skill, information,

seasoned judgment, and personality qualities adapted to the requirements of his circumstances. But the same power also gives to the passing years the opportunity for learning powers to fall into disuse and atrophy, for undesirable habits of thought, action and personality to form, harden and to escape from conscious control or even conscious recognition, and for the crystallized habit structure to become fortified in bias and complacency. Psychologically, what the advancing years do to the worker or executive is thus essentially dependent upon what he does with the years. As to those qualities of intellect, feeling, and character which can be exercised and developed in leisure—they are primarily within his own control.¹ But under the exacting job control of modern management, junior executives as well as manual and clerical employees must largely depend upon the higher management for determining whether their jobs render the passing years' steps toward development or obsolescence. Of course, the individual can and must do much; but the more highly industry is organized, and the more standardized the work of the individual, the less can he influence the nature of his job, and the more the nature of his job determines his qualifications as a worker in middle age.

Human nature is thus psychologically equipped to meet the fundamental requirements of modern industry and scientific management throughout middle age as well as youth. Within an individual plant the difficulty arises when scientific management is not applied scientifically, but in a haphazard way; when spasms of change follow in the wake of managerial stagnation or failure. Even a motor car or a horse rebels against jerky driving. If the application of scientific management is to avoid middle age obsolescence, it must be consistently as well as effectively applied. Unfortunately the external problem is more baffling. Under modern manufacturing conditions, even when continuous development is made, the work in one industry is highly specialized compared to that in another. Even individual companies have highly characteristic practices and methods. In proportion as service is long the habits of the employees in regard to fundamental company and industry responses become set. Change to another company and especially to another industry involves not only beginning again but an immense amount of unlearning. Moreover standards of living have become firmly established by middle age, and make the long process of working up again from the starting wage a bitter experience. And yet, with changing market demands in many industries and more rapid increase in productivity than in market demand in others, such inter-industrial re-distribution of employees seems inescapable, and such re-distribution middle age is ill-adapted to meet. Consequently care should be taken that so far as possible this distribution is confined to the younger workers.

Human Nature Plastic. Human material is remarkably plastic, but it cannot be held for years in one mold until it is thoroughly hardened, and then be forced abruptly into another. In general, when men become psychologically obsolete in middle age it is not a sign that they can no longer conform

¹ With the worker much, of course, also depends upon the provision by the community of facilities and leadership to assist him in rendering adult recreation a force for adult education.

to the demands of modern industry or to the progress of engineering development, but either that the mistakes and irregularities of management have required them to assume excessive psychological burdens or that their obsolescence is a consequence of the rapid changes in distribution of labor involved in the present readjustment of production and consumption.

THE EMPLOYMENT AND ADJUSTMENT OF THE OLDER WORKER

BY C. R. DOOLEY, *Manager, Personnel Department*, and HELEN L. WASHBURN, *Standard Oil Company, New York*

Every day the personnel man or woman must face questions concerning the employment and adjustment of people, their compensation, their conditions of work, their training, their advancement and their records—and must look at these questions not only from the employee's point of view, but from the management's point of view.

But no problem in the personnel field has proved more difficult than that of the older worker. It is becoming increasingly difficult to find a new place for a person past youth—either by transfer in his own company or in another company. By "older" we do not mean elderly people, but those of middle age—say past forty.

Seventy-five companies, nearly all members of the American Management Association, were questioned on this subject. They are located in the Middle West, in the South, in New England, and here in the East—eleven states being represented.

They are representative organizations: public utilities, such as gas and electric companies and telephone and telegraph companies; department stores; street railways; life insurance; petroleum; bond houses; and manufacturing, including textiles, paper goods, rubber goods, metals, stoves, chemicals, paints and enamels, gun powder, electric supplies, and sewing machines. It will be seen that the information gathered came from a pretty wide field.

A list of questions was sent to the selected companies, covering the difficulties encountered in connection with older people, and the methods used to meet these difficulties, and asking for opinions and suggestions on the subject. Replies were received from sixty-four companies. These replies indicated an active interest in the problem of the older worker.

The Chief Causes of the Problem. This problem of the older person in business and industry has various aspects. It must be viewed from the employer's point of view because he has his own problems in connection with it. Then the older employee (the man still inside) faces it from a different angle. And the older applicant has his own difficulties when he is trying to get into a large organization from the outside. We shall probably speak of employees and applicants as though they formed one group, because the line between them is, after all, a very narrow one; the moment an older employee loses his position, he becomes an applicant to another department if not another company.

There are various reasons for the situation, but evidently the chief causes are as follows:

Age Limits. First, the age limits. These are of two kinds—there are the fixed age limits set by a limited number of companies, which exclude people over forty or fifty or fifty-five years of age. Only nine of the companies answering have definite, written rules as to age at the time of employment.

The large majority of companies do not have formally established age limits, but do have a tacit understanding that the employment office should not take on older men and women. However, in practice the age limit works out much lower than these established limits—due chiefly to the policy of employing young people and training them up in the business.

There were twelve times as many answers admitting that in practice the hiring age is much below the established age limit, as those taking the opposite view.

Policy of Promotion from Within. As has already become evident from the above, the age limit is also brought about by other factors than the arbitrary rule set by a company, and the exclusion of mature people is frequently automatic—not intentional. One strong factor is the policy of *promotion from within* which is followed consistently by practically all large companies. Under this policy about the only openings for people from the outside of the company are those at the bottom of the ladder and about the only advanced openings for outside people are for those with very special kinds of experience.

Pension Plans. The pension plans of most of the large companies also help fix the age of employment. These plans usually require a certain length of service before pension, usually from fifteen to twenty-five years, although a very few companies only require ten years. As the retirement age is generally set at from fifty-five to sixty-five years, a new employee must be under forty or forty-five years in order that the company may obtain the requisite number of years of service before pensioning.

Yet while this factor undoubtedly does affect the age limits for employment, an analysis of the replies on the point reveals that the number of companies which do not have pension plans is nearly twice the number having such plans.

Reorganizations and Mergers. The many reorganizations and mergers which are taking place today also affect older workers. Despite their advantages and their necessity from an economic point of view, they nearly always result in a cutting down of forces; and the older employees who are frequently slower, not so easily transferable and higher salaried than younger ones, are most often released.

Older People's Characteristics and Peculiarities. Then, too, the personal characteristics and peculiarities of the older employees increase their difficulties. The individual who has not become "set" and who has not developed some traits of mind and manners, which make him hard to fit into a new place, is rather rare.

The companies questioned agreed on this point in the ratio of four to one, although it is only fair to say that perhaps a third of them made no definite comment on it.

Problems Confronting the Employer. In addition to the chief causes of the problem, which were discussed above, there are certain factors—or sub-problems—which must be considered before the question of solutions is taken up.

Older Employees Grown Ineffective. The problem which is probably most frequently encountered is that of the older employee who has grown ineffective in his work and who sometimes is beginning to be physically disabled, when he has a good record and long service. What is the employer to do in his case—carry him on at the same pay, which is not really fair to employees, who are doing efficient work at the same pay, nor fair to the company? Or carry him on at reduced pay—which is hardly possible because the mature employee usually has definite responsibilities and cannot take lower pay? It is extremely hard for the employer to give such an employee simple work with adequate compensation. It is difficult to transfer him because his salary is too high for a beginning opening, yet another department head is reluctant to put him in an advanced place to which he naturally wants to promote one of his own people, and for which the candidate has had no special experience.

Employees' Positions Abolished. The replies to the questions: Have you had occasion to terminate employees of middle age and long service? How frequently? Under what conditions? analyze as follows: More than half of the companies stated that they have seldom found it necessary, and then only for extreme reasons. Those who have had occasion almost all modified their statements by explaining that such terminations usually had specific causes. Thus it will be seen that companies do not readily terminate older employees with good records.

Transfers. Transfers are the solution for a number of the problems connected with the older worker, yet that they themselves frequently present a problem or difficulty to the employer was affirmed by the majority (more than two to one) of the companies answering the question on this point. And his difficulty is not only with the older employee, but with his department head.

General Lay-offs. Another occasion for difficulties with older employees is at times of general lay-offs—whether temporary or permanent. The replies to the question concerning policy and practice in lay-offs about releasing people according to length of service or according to age, and about reemploying such people before taking on new, indicate that almost all companies make it a point to retain people who have been with them the longest time and to re-employ these people first when the lay-off is past. Half a dozen companies stated they do not have the problem and so have no policy concerning it. However, it is noticeable that many companies stress efficiency or good service equally or more than long service. An employee must have a good record as well as years of service to his credit before he can be sure of being taken back.

Executives and High-salaried Men. The problems connected with executives and high-salaried men are always particularly difficult to solve. It is very hard to transfer such people because in another department they cannot be placed over those who have been there for some time. Yet if they are given work at a lower plane, it is very hard for them to accept the necessary cut in salary.

The Loss of Older Peoples' Experience and Skill. Naturally most of the concern felt over the problems connected with the employment and transfer of older people is directed towards the workers themselves. Yet there is a strong feeling abroad that business and industry are losing something when able mature people are barred from their employ either because of an arbitrary rule or because of certain conditions. Evidence of this feeling is contained in the replies to the question: Do you feel that business and industry are losing valuable assets when because of rules and regulations, they are unable to employ mature people with their accumulation of experience? The companies agreed four to one on this point, and expressed themselves quite definitely.

Loss of Independence and Initiative. The question, Does the tendency to hold employees for long service tend to destroy their independence and individual initiative? was evidently not quite understood by some of the companies approached. The point in mind was: Does the feeling that if a man finds himself inside a large organization, he had better call himself lucky and stay there for the rest of his life, weaken if not destroy his courage, independence and initiative. A man or woman of middle age must be very careful nowadays before leaving a position—no matter how unhappy or no matter how much he or she wants to do something else—because it will be so hard to get another place. The majority do not think that long service in one company tends to lessen independence and initiative.

Problems Confronting the Employee. The employee's problems are really the reverse of the employer's problems. They will, therefore, be reviewed briefly in the following paragraphs since they have been discussed indirectly in the preceding sections. There is no intention, of course, to minimize the difficulties confronting older workers by this brevity.

It probably will be agreed without much argument that if a person continues to be efficient, mentally keen, in good health, industrious, cooperative, open-minded, and interested in his work, he or she will be successful and satisfied in his or her business life, and will neither be nor have any serious problem. Where difficulties occur in connection with the transfer or employment of an older person it is usually because he or she is not quite up to standard or "desirable"—hard as this may be for him or his friends to admit.

We will not again go over the difficulties connected with the *transfer* of an older employee; first, because while he may be worried when the company cannot seem to find another place to put him, he is still safe inside; and second, the question of transfer is more the employer's problem and it is he who has to solve it.

It is when an employee is actually *terminated* and becomes an applicant that his real troubles begin. If he has put in long years of service with one company, his habits have grown fixed and he usually knows only one line of work. Frequently such experience is of little or no value to another company. Indeed, he is often asked rather pointedly why his own company did not keep him after so long a connection.

A man or woman of middle age nearly always has definite responsibilities such as a home and a family to maintain; he or she must have a steady income and often cannot go below a certain salary. An excellent comment on this

point was made by one of the companies, even though it does represent the employer's point of view:

One of the difficulties in hiring older employees is the starting salary. We have a job classification, and we do not exceed our salary range except in exceptional cases. A man of forty may tell you that he is willing to come in at a runner's wage, but if you take him at that, you usually have a discontented employee and likewise often very unfavorable comments from the outside. For example: a man applies for a job and is willing to take anything. He is totally out of work and has a wife and several children. The maximum on the only opening for which he is fitted is \$1,000 a year. If we take that man, we would very soon hear comments on how badly our employees are underpaid; how the families were almost starving—which would, of course, be somewhere near the case under these conditions.

One reason why his termination frequently gives an older employee a very bad jolt is that his employer has not been sufficiently frank with him all along. He has not only been retained, but sometimes he has received salary increases based on his length of service rather than on merit, although all the while his employer has not been really satisfied with him. That this is a recognized situation is well illustrated by the following quotations:

In our training of supervisors and executives we continually emphasize their responsibility in scrutinizing the work of new employees in order to determine whether they have or have not sufficient ability to warrant their permanent retention in service. We teach them that it is a serious reflection upon them to hold an employee as long as four or five years on their payroll and then suddenly discover that he is not qualified for our work. It seems that any capable executive ought to be able to reach a conclusion in matters of this kind before the employee has had more than three years of service. The unfit should be weeded out early. If they are not, we, as a company, certainly incur an obligation because we have deprived them of a chance to make good in other fields.

It is management's duty to educate their foremen to weed out undesirable workers early in their service. If possible, employees should be transferred within the department during vacations, sickness, etc. New jobs are posted, thus throwing somewhat the responsibility back to the worker in case he has never tried for another position. All men of long service are checked periodically and when their production is falling off, steps are taken to seek other work for them before the situation becomes acute. This "labor loan" or temporary transfer policy under the unemployment fund has educational influence toward training for versatility.

Finding Another Place. In this matter of finding another place the older person is apt to go round in a vicious circle. To begin with, he is released because he is not quite up to standard. If he has a long hunt for a position, he is put under a terrific strain; he loses his perspective, loses his nerve, loses his good bearing and sometimes his good appearance. Thus it becomes increasingly hard for him to make a good impression on a prospective employer.

Suggestions to Employers. Open Mind Regarding Age. It will help ease the difficulties connected with placing older people, if employers will view the question of age with a more open mind. The studies of Professor

Thorndike and others have settled beyond much further question that older people can learn new things and can adapt themselves to new conditions. This being the case, it seems unfair—to say the least—not to give them a chance at new work. The older employee not only has his place, but his real value in the business and industrial world.

Company Policy Regarding Employees of Long Service. More than this, a company should have a definite policy regarding its older employees, and should see that department and division heads cooperate in carrying out this policy. In connection with this it will probably be necessary to cultivate the "company" in place of the prevailing "department" point of view.

We have already seen that companies have a definite policy of protecting older employees in connection with lay-offs. Practically all of the companies approached (there were only two exceptions) have just as definite a policy about retaining older employees when they have lost their full usefulness but have not reached the pension age.

Training for Older Employees. The question as to what educational plans the various companies have to increase the versatility of their older employees brought the information that not one gives special training to this class of employees. However, this statement must be qualified by the fact that the majority of the companies give general training—both by courses and on work—to all types of employees in order to increase their efficiency and versatility. As their comments will show, the companies feel that their older employees benefit from such training along with the others, so there is little need for them to have any special instruction. It is undoubtedly true that as time goes on the great majority of employees in large organizations will be so well trained that not only will their efficiency on their special line of work be brought to a high level, but they will be well acquainted with various phases of their company's business—thus increasing their adaptability and "transferability," and ending one of the chief difficulties connected with older people.

Consider Older People in Reorganizations and Mergers. While reorganizations and mergers cannot and should not be stayed because of individual considerations, it seems the part of wisdom as well as fairness to retain as far as possible older employees who are frequently steadier and have better judgment than many younger ones and whose knowledge of the business is a factor not to be ignored.

Transfers. Since it is frequently quite difficult to transfer older or advanced employees, employers will be interested in the following quotations which tell what these various companies do in connection with such transfers: For one thing they were unanimous in stating that they do everything possible to transfer and not terminate employees whose work has been done away with. In this group of replies is also discussed the practicability of transferring older employees to positions of lesser responsibility and reduced pay. Contrary to what might be expected, half of the companies have found it practicable to transfer them to lesser positions at reduced pay. About one-quarter of the companies said that they have continued these employees at the same pay on positions of less responsibility. Only half-a-dozen companies have not found it practicable to make this sort of arrangement.

Terminations. The replies to our question as to what special arrangements these companies make upon termination if a transfer cannot be effected, are particularly interesting. They analyze about as follows: Only three companies do not make some arrangement; three companies pay such employees from a fund—pension, unemployment, benefit, or service fund; ten state that they practically always effect transfers and do not have to terminate; and over half say they make special payments to these employees, if a termination becomes absolutely necessary.

Abolish Age Limit Rule. Since the majority of large companies do not have fixed maximum age limits for employment and in view of the employers' sincere interest in older employees and applicants, and considering the value of mature people in business, there seems no good reason why an arbitrary maximum age at the time of employment should be adopted. Men and women in good health should be given fair and full consideration for openings regardless of age.

Of course it is not quite so simple to eliminate those factors which automatically bring about age limits, although it is believed something can be done along this line if employers make a conscientious effort.

Modify Pension Plans (or Waive). For instance, it is plainly possible to lessen the effect of pension plans upon the employment age by grading pensions according to years of service under twenty years or by employing middle-aged people with the clear understanding that they will not be eligible to pensions upon retirement owing to insufficient length of service. This is now being done, as the replies indicated.

Promotion Policy. It seems agreed beyond further question that the policy of promotion from within cannot be changed or modified. It is only clear justice to have such a policy; it builds a strong, efficient and lasting organization; it lowers turnover; its disregard would have a most disastrous effect on the morale of a company; and it is the only outlet or reward for the increasingly large number of people who have become part of the great organizations and combinations which are taking the place of individual efforts. This is agreed to by applicants, as well as those within a company—all say that if they were inside, they would be only too glad to know that the company would recognize merit by promotion and would not put anyone from the outside over them. Not one has been encountered who was so resentful over the conditions which shut him out that he was ready to criticize the attitude of a company in advancing its own people.

Suggestions to Employees and Applicants. Despite the sincere sympathy and interest felt for older people faced with the difficulty of finding a new place in office or plant, it is generally agreed that they themselves are responsible for many of their own problems. This statement is not made coldly—but simply because the sooner older people realize this responsibility, the sooner they will set to work to correct the traits and shortcomings which are hindering them. And it is in this spirit that the following suggestions are offered to them.

Keep Work up to Standard. One thing that is absolutely necessary is that an employee make every effort to keep his work up to a high standard. In fact, he should try to become recognized as above the average. This is a day

of keen competition and no man (and no company) can afford to slacken. We have seen that companies give older employees every consideration in any crisis, but in turn they require efficient and conscientious service from the employees. While companies make many efforts in behalf of such employees, they refuse to say they are "obligated" to retain them regardless of quality of work.

Expert in Some Line. The man who has made himself an expert in some line evidently has a decided advantage over the man of general experience. In the first place if his work is of particular value, his own company is apt to keep him. If it does become necessary for him to find a new place, age limits may have to be waived in his favor if he is considered very good in his line. This is well illustrated by the replies received in answer to the question as to whether the difficulties encountered in employing mature people varied with those of specialized experience and those of general experience. More than half of our correspondents said they can do more for applicants of special experience.

More Than One Line of Work. From the comments just preceding, it is evident that while it is a good thing for a man to be especially qualified for certain work, there is some danger that he may be hampered at times by knowing only one line. It will be especially helpful toward transfer in his own company, if he knows several phases of its business. For this reason he should avail himself of every bit of training he can get and of every variety in work which may be offered him. The more he can learn relative to his company's business, the better. If outside study or reading will help him, he must not fail to add to his equipment by this means.

Attitude. Since it is pretty well agreed that the difficulties of older people are due in no small degree to their being set in their habits of work and of thought, not sufficiently adaptable nor teachable, not cooperative with associates, and above all not open-minded enough to new ideas and customs, it surely behooves them to watch out for these middle-age tendencies.

It is quite commonly recognized that a person's physical age and his mental age may be very different. It may not be possible for him to actually control the former, although care and good habits can do much to prolong full vigor, but he himself is largely responsible for his mental age. He should try continuously to keep alert and interested, and to keep a contact with the viewpoint and ways of younger people—whether or not he approves or follows all of them. It has been well said that "It is a bad thing to be out of step with your times."

If Transferred. If an employee finds he must be transferred, it is often better for him to accept the transfer and to stay with his company even if it involves a lower position and less pay. This often proves only a temporary situation, and a little later he finds himself advancing in his new place—especially if he takes trouble to learn his new work.

Finding Another Position. If it does become necessary for an older person to find a new place, his success will depend a good deal upon how he goes about it. First he should estimate his *assets*—his experience, his education, his personal qualities, and his contacts or alliances.

Then he should estimate his *liabilities*—has his experience been either too scattered or too narrow? Has his education been too limited? Is it practical, technical or academic? Has he neglected educational opportunities available during his spare time? What personal qualities does he have which hamper him: is he too individualistic, or on the other hand is he so much an "organization man" that he is lacking in originality and initiative? Is he impatient or egotistic? Does he disagree with too many people?

He should next appraise his probable value to a prospective employer. Probably he can offer the most in the line in which he has had most experience. Therefore he should apply to companies which use men for his kind of work. There is less chance with the larger companies for an older applicant, since they usually have some rules and policies which bar the employment of older people, and more particularly since they can usually fill their openings from inside.

Suggestions to Older Applicants. While frequently the employment manager cannot employ an applicant, he is glad to give a helpful suggestion and often does so, although it is difficult to offer concrete and practical suggestions. It is evident, however, that almost every one makes considerable effort to help older people. The most frequent suggestion is for them to try one of the smaller companies, since they are less apt to have age limits. Another suggestion is in regard to companies which have work for which the applicant is especially fitted; although some suggest to the applicant that he try to change his line of work, and so adapt himself to conditions. A good many companies refer such applicants to special agencies, such as trade or industrial associations.

The older applicant should watch his own attitude while seeking a new place. He must not lose his self-confidence—he does not need to because he is needed in the business world; it is only a question of finding the place where the need is acute. His accumulation of experience and knowledge are assets which the younger person cannot offer. He must not get a biased view because he is going through a trying experience; and he must not harbor a feeling of soreness over his situation, because that will only hamper and injure him.

Conclusions. A few facts stand out as we review this study: For one thing the companies all have an attitude of loyalty to their older employees; they practically never release one with long service and a good record. (It seems justifiable to say "all," since sixty companies replied to the questions, out of seventy-five who were approached.)

A good record takes precedence even over length of service and age.

Companies are sincerely interested in and sympathetic with older people's problems—those of applicants as well as employees.

It is very generally agreed, however, that older people's personal characteristics and peculiarities are obstacles in the way of their transfer or employment.

Few of the companies approached give special training to older employees, feeling that their general training benefits this class of employee along with the younger ones.

While there are no definite solutions, some of the suggestions made and practices followed would greatly alleviate the situation, if adopted generally by employers and older employees and applicants.

If the age limits continue to cause so many difficulties, some changes will have to be made. The group of companies were asked what they thought would be the ultimate results if the practice of establishing maximum age limits should continue. The viewpoint of a number of the companies is expressed in this statement made by one of them:

There can be no question whatsoever, but that the locating of large groups in corporations with regular systems of training, promotion and advancement, makes difficult the employment of mature men. Many men of high calibre and wide experience apply to the big corporations for work, but find no vacancies because of the excellent system the corporations use in preparing their young men for positions which may become open. Frequently mature men find themselves out of work after long tenure of office, on account of reorganization and improved methods of procedure. They are dropped through no fault of their own nor a desire on the part of their company to lose them, but merely because their work has been abolished. Every man of this type who is unable to locate another position becomes a serious unproductive loss to his community; also it results in hardship to him and his family. Therefore, unless industry takes this problem in hand and solves it, it will grow to a point where resort will have to be had to legislation.

RELATION OF MAXIMUM HIRING AGES TO THE AGE DISTRIBUTION OF EMPLOYEES AND TO THE PROBLEM OF UNEMPLOYMENT AMONG OLDER WORKERS

BY MURRAY W. LATIMER, *Industrial Relations Counselors, Inc.*

We have recently been hearing on all sides that industry has in late years begun to restrict the hiring of new employees over certain ages, sometimes cited as forty-five, usually in 1929 as forty. It is being asserted that these limits on hiring are well-nigh universal, and that their operation is causing an unprecedented amount of unemployment at ages above forty-five. This paper will attempt to trace the development of age hiring limits and make some analysis of the causes and present extent of their use. Some effort will also be made to ascertain their relation to the problem of unemployment among older workers. The material presented deals mainly with the wage workers. Statistical evidence is rather difficult to find on executives. For that reason, I have so far as possible excluded them and clerical workers as well although certain of the data presented here includes both classes. For executives especially, the data on hiring age limits have little application.

Restriction of Employment of Older Persons a Problem since the Beginning of the Industrial Revolution. It is most significant to remember that beginning with the industrial revolution, the entrepreneur, as an incident to the introduction of the factory system, gained control over his labor force more completely than he had under the domestic system. In previous systems where the employer did have complete control of the worker, either the

connection was life-long as in serfdom and slavery, or there was some opportunity for advancement as in the early stages of the handicraft system.

It was inevitable that the employers should use this newly acquired control over their working forces to reduce, in so far as possible, their labor costs. Under the *laissez faire* régime, competition became so severe that failure to utilize cheap labor was regarded as the equivalent of financial ruin. The utilization of child labor, the cheapest, was facilitated, of course, by the growing use of machinery, which was coincident to a considerable degree with the spread of the factory system. Among the many characteristics of machinery, two are important in this connection: (1) it enables less skilled persons to do the work formerly performed by persons of skill and experience, and (2) it permits employment of persons possessing less physical strength. The way in which this conjunction of events at the beginning of the industrial revolution was used by employers to fill their factories with women and children, need not be dwelt upon. Rather, the lessened employment of the older worker will be emphasized.

Allegations that elderly persons find it difficult to obtain gainful occupation probably have been heard in all ages, but for our purpose it is sufficient to observe that they had begun as early as 1818 when the London tailors objected that their period of usefulness was being shortened by the nature of their work. This, of course, was prior to the introduction of the factory system in the trade. Out of 405 journeymen tailors frequenting one house of call in London in 1818, only 4 per cent were of the age of forty-six or over and less than 1 per cent were as old as fifty-six. It was also stated that no one of those of forty-six years or over was regularly following his business as a tailor.¹

An official British commission stated in 1909:

It must, however, be remembered that the complaint of an increasing tendency to replace elderly men by the young is one that is always being made. In particular, it is to be traced as a constant refrain at every decade of the past century. In 1839, for instance, it was officially reported, as a partial explanation of the unemployment among the hand-loom weavers, that "a great majority, including those who are past fifty years of age, or who from any cause do not possess the requisite skill, quickness of sight and strength have great difficulty in getting employment to enable them to live." In 1848 we read, in terms that sound familiar, that "Workmen . . . are discharged as soon as grey hair appears, or a pair of spectacles is attempted to be used; many of the workmen straining their sight to the uttermost before they give in to be turned adrift through wearing them." "Old carpenters," it was said in 1850, "are generally despised by master builders; the failure of sight and wearing of spectacles is almost a death blow to many a good old tradesman. And in many cases a master will not give an elderly man employment at any price; the consequence is that many have been compelled to go to the parish for relief or into the Workhouse. Employers instruct their foremen to deny a job to men above a certain age." And further, "it is one of the chief evils of the carpenters' trade that as soon as a man turns forty masters won't keep

¹ United States Bureau of Labor, *Bulletin* 62, pp. 762-765, January, 1906, citing the *Gorgon*, pp. 154-160, Oct. 3, 1818.

him on." What was said in 1839 and 1848-50, was being said in 1894—still prior to the Workmen's Compensation Act. "Throughout the entire field of industry the shortness of employment is most largely represented in the progressive underemployment of the middle age. In many departments of labor, for example, among miners, sailors, mule-spinners, in metal and machine making, it is practically impossible for a man to have any security of work over the age of forty-five or fifty." We suspect, indeed, that the same thing has been alleged ever since the master craftsman, himself producing and selling his own product, was replaced by the capitalist hirer of labour.¹

Among the later recorded protests of the organized workers against the hiring policies of employers was one in 1887 in England, when the Amalgamated Society of Engineers complained that age limits were seriously restricting the opportunity for employment among their older members. In the thirty-seventh annual report of the society, it was stated that: "there is another powerful factor which is now prevalent in our government workshops, railway companies and municipal corporations and nearly every large establishment throughout the United Kingdom have a standing order that no man is to be engaged over forty years of age."

The volume of complaint against the prevalence of age limits in industry increased to such an extent that the Royal Commission on Poor Laws and Relief of Distress appointed in 1905 (from whose minority report the quotation given above was made) took occasion to make an investigation. In the minority report of the Commission, it was concluded that the discrimination against the older worker was largely fictitious.² No evidence of any decline of the average age of those employed either by particular firms or in whole trades was discovered. Statistics from the British trade unions indicated rather that the age of industrial workers was steadily increasing. The age distribution of a sample of the unemployed indicated that only 2.7 per cent were over sixty, while 80 per cent were under fifty.³

One observer testifies that there appears at present to be an unwillingness among British employers to take on new elderly employees. He says:

So far as I know, there is not in any large corporation a fixed rule in regard to a maximum age at which an employee is hired. While, however, such a rule does not exist on paper, it nevertheless is a practice to refrain so far as possible from taking a man on at any age above, say, forty-five. You would not be in order, however, in concluding that British industry generally regards a man as being too old at forty.⁴

A sample study of the unemployed in April, 1927, made by the British Ministry of Labour, indicated much heavier unemployment among men fifty-

³ In 1911, 3.6 per cent of those gainfully occupied in Great Britain were sixty-five and over.

⁴ Letter of R. Lloyd Roberts, Imperial Chemical Co., London, to Murray Latimer, Aug. 13, 1929.

five to sixty-nine than for any other age groups. On the other hand, the proportion of unemployment among men forty-five to forty-nine was less than for those from twenty-five to twenty-nine (and that for men fifty to fifty-four was but slightly greater).

Age Restrictions in the United States. In the United States, assertions that hiring age limits were restricting the employment of older men, seem to have begun at a much later date than in Great Britain. Protests were numerous about 1900, especially in regard to railway employment, both steam and electric.

In the studies of steam railway employment in the United States, made prior to 1900, age limits for employment do not seem to be mentioned. In a report published in 1901 it was stated, however, that the "age qualifications have changed greatly in recent years and are now uniformly lower than they were ten years ago. It is now difficult for anyone over thirty-five years of age to enter railway service without previous experience and many do not employ men at all over this age."¹

In this 1901 study, four railroad companies operating 19,255 miles of road with 172,384 employees (of a total in the United States of slightly over 1,000,000) were examined as being typical. On the first road, train service employees, brakemen, and firemen, were not to be employed at ages over twenty-seven; conductors and engineers were to be promoted from the ranks of those so hired. Mechanics were not to be over thirty-five. All were to pass a physical examination or produce evidence of good health. On the second road, transportation and mechanical employees were to pass a physical examination, as were trainmen and engineers on the third road. On the fourth road, which employed almost 68 per cent of the employees covered in the survey, the maximum hiring age in any occupation was to be thirty-five.

Although no reasons for the limits were given, the implication was that they were due mainly to conditions surrounding the job, particularly the necessity of taking no chances in the interest of public safety. It is probable also that the seniority rules of the railroad labor brotherhoods were a factor. In 1905, a canvass by an investigator in the United States Bureau of Labor showed that the general age limit for newly hired motormen and conductors on street railways was forty. Actual hiring age limits on fifty-three systems ranged from thirty-five to fifty. The investigator had the following to say about hiring age limits:

Progressive shortening of the trade life by reducing the age at which men can enter employment is felt by many of the men as a great hardship, and is used as an argument to show the difficulty and nervous strain and the unfavorable conditions surrounding the work. In the old horse-car days a man of forty-five would ordinarily secure a position with the street railways, but now the tension and strain is felt to be so severe that the age at which new men are taken on is gradually lowered. On the average there are some eighteen years between the average minimum and the average maximum age at which men may be admitted into the service. The establishment of a low maximum like that of thirty-five years tends to force employees above the age limit to

¹ LINDSAY, SAMUEL M'CUNE, "Railway Employees in the United States," *Bulletin of the Bureau of Labor* 37, p. 1032, November, 1901.

become extremely cautious and conservative in the maintenance of their present positions.¹

Data as to the age and length of service of employees at retirement, which have been collected in the course of a pension survey conducted by Industrial Relations Counselors, Inc., indicate that the use of hiring ages for men on railroads began as early as 1870, probably earlier. There is also evidence that the age of hiring declined from the early seventies to the nineties, and after the middle nineties rose slightly. The nature of the data is such that historical evidence after the beginning of the twentieth century is not available.

So far as we have been able to determine, all the existing hiring age limits on steam railroads began more than twenty-five years ago; most of them antedate the establishment of pension plans. All the changes in railroad hiring age limits—four—which we were able to discover were in an upward direction, one being abolished entirely.

Data of the same sort for the steel industry indicate that the ages of employees hired were declining as far back as the 1880's. No increase in the average hiring age had appeared by 1895.

This brief survey suggests that the problem of hiring age limits in industry is an old one; that the origin was technological, and lies in physical conditions pertaining directly to the job rather than in extraneous conditions. The question, therefore, is whether the age limits which exist at present are still due primarily to these same causes, or whether additional reasons are now operating to perpetuate them.

Extent of Hiring Age Limits in 1929. First of all, it would be advisable to determine just what the hiring age limits are as of the present day. In the course of the pension survey already referred to, Industrial Relations Counselors, Inc., attempted to discover from firms maintaining pension plans whether or not a hiring age limit was in effect in the company, and if so, what it was.²

Returns were received from this inquiry as shown on page 1325.

In 101 of these 239 companies reporting the number of employees, or 42.2 per cent of the total, there was no age limit for hiring. These companies employed a little less than 26 per cent of the total number of persons covered by the survey. Ninety-five companies, or 40 per cent of the total, employing 61 per cent of the persons covered, either refuse or require high executive sanction to engage for their service persons over certain ages. Forty-three companies, or 18 per cent of the total, employing 13 per cent of the men, placed no restriction on the age of hiring but did not extend eligibility for pensions to persons hired over certain specified ages.

¹ WEYL, WALTER E., "Street Railway Employment in the United States," *Bulletin of the Bureau of Labor* 57, pp. 565-566, March, 1905.

² Certain limitations must be borne in mind. It is confined to companies with pension plans. Most of the reporting companies are large. It should be noticed that the very important construction industry is not represented at all in this survey. Whether the proportions derived from this sample apply to companies for which no return was made or those outside the scope of the survey is, of course, doubtful. The samples of the railroads and public utilities, however, are so large that it is fairly safe to infer that they are representative of the whole of their groups.

Companies maintaining non-contributory pension plans	Companies answering questions	Companies reporting number of employees	Number of employees
Manufacturing.....	87	85	1,010,505
Railroad.....	39	39	1,374,836
Public utility.....	47	46	518,648
Banking and insurance.....	21	21	62,154
Others.....	12	11	39,019
Total non-contributory.....	206	202	3,005,162
Companies maintaining contributory plans.....	42	37	108,563
Grand total.....	248	239	3,113,725

The differences in policy between various industrial groups were striking. For example, 76 per cent of employees on railroads were in the service of companies maintaining the so-called age limits, as were almost 90 per cent of employees in public utilities. Of the total number of employees in companies selecting as new employees persons under certain ages, almost 80 per cent were in these two groups. On the other hand, only 33 per cent of employees in manufacturing industries were in such organizations, and they represent but one-sixth of the employees in all companies having age limits for new workers. It is evident, therefore, that among public utility and railroad companies the chances of obtaining employment in companies with a pension plan are quite small for a person over the age limit, which is usually forty-five. On the other hand, his chances of obtaining employment in manufacturing appear to be two to one, and there is even greater likelihood of his being employed without loss of pension privileges.

A word about the restrictions in public utilities is in order. Some of the large companies in this field have a virtual monopoly on their branches of the industry. The work is highly technical and, much of it, unique. In order to obtain an adequate supply of competent employees, they must be hired when young and trained for a long period. Normally, these companies expect to keep such a person for life; there is usually, moreover, no other occupation in which the peculiar training could be utilized. On the other hand, persons over the age limit are quite frequently hired for jobs for which their training fits them.

A recent study made by a committee of the National Association of Manufacturers indicates that only 28 per cent of the number of companies making returns impose hiring limits.¹ Of the eighty-seven companies in manufacturing making returns for our inquiry, only twenty-one, or 24.1 per cent, impose such limits. The number of establishments covered by the questionnaire of the National Association of Manufacturers, the nature of

¹ *American Industries*, vol. 30, No. 3, p. 62, October, 1929, New York, 1929.

their business, the number maintaining various types of benefit plans, and the number of employees is not given, so that no definite conclusions may be reached. The implication is, however, that manufacturing companies maintaining pension plans are not more likely to impose age limit restrictions on hiring than is a company which does not have such a plan.

The hiring age limits as brought out by our study vary widely. A few companies have a policy of promoting only from within their own ranks and doing all the training themselves. The hiring age limits are, therefore, very low. Of the ninety-six companies maintaining hiring age limits, fifty-three had a maximum of forty-five, and fourteen of forty; in fifteen it was thirty-eight or lower, and in fourteen the limit was fifty or more.¹ These ages given represent the maxima. In certain occupations, especially for train service on the railroads, the entrance ages are much lower than the maximum for the road.

In the companies whose restriction concerns eligibility for pensions rather than hiring age, the maximum age set was lower than forty in one case; was exactly forty in eleven; between forty and forty-five in thirty-one; and fifty or over in eight.

There are some indications that the hiring age limit is connected with large scale operation. It is noteworthy that the largest companies reporting in each industry were those which maintained hiring age limits. Of all the companies in our sample, the average number of employees of those maintaining no age hiring limit is about 8,000; companies having a hiring limit, about 19,000; and for those with maximum eligibility limit, a little less than 10,000. These differences in size persist through all types of industry. For example, in the manufacturing industries, the average size of companies with maximum hiring ages is over 15,000; maximum eligibility age, a little less than 10,000; and companies with no maximum, about 11,000.

This difference in size suggests that these large firms, because of better management, can establish definite policies, but that the smaller ones are often more haphazard in their methods and hire and fire at random. Moreover, the larger firms can usually find suitable men for promotion from among their own employees, whereas the smaller company may frequently find it necessary to obtain the proper person for a particular job outside the company. Again, the jobs in a large company are likely to be more specialized so that relatively more of them are suitable for old persons than would be the case in smaller companies in which each employee performs a wider variety of tasks. The introduction of trucks, cranes, automatic lathes and similar devices in many cases tends to reduce the physical effort required and offer certain jobs to men past the prime of life. Jobs capable of being filled by older persons are, in these larger companies at least, reserved for the men who have grown old in the service of the particular company. Hence the age limit against the others. On the other hand, speed in movement—of body, or arm, or eye—is a necessary qualification for certain jobs. Not only speed, but also unusual bodily strength may be demanded of employees in those industries,

¹ The number of companies in these totals differs from the totals given on p. 1325; nine companies are included here which made no return as to number of employees.

or sections of industries, usually characterized by large scale mass production, in which the pace of work is set by a machine or moving belt. Workers are less able to meet these requirements as they grow older. An interesting sidelight on this aspect is that immigrants who were in industry before coming to this country frequently prefer employment in small organizations and refuse to work in large establishments. There are, therefore, divergent influences at work, some of which tend to facilitate employment of older workers, though this tendency may be limited by imposition of hiring age limits, so far as the actually unemployed are concerned; other influences tend to limit the use of older persons.

The existence or absence of hiring age limits does not indicate whether the influences tending to reduce the employment of older persons or those tending to increase the number are preponderant. An investigation of practice rather than of policy is needed.

The need for such an inquiry is brought out also by the fact that the age limits given here are taken from questionnaires which merely asked whether or not a maximum hiring age for employees had been established. One of the disadvantages of this method of obtaining information has been that for the most part we were unable to discover whether the limits are effective or ineffective. That these objections have considerable reality is made manifest to us by examination of detailed records of a few companies. In one company having a hiring limit of forty-five years, about 2,000 persons over the age limit were newly employed during the last two years. Similar figures can be cited for other companies. In cases where no formal policy exists, on the other hand, the actual practice may result in limiting entrants to young persons. For example, a company was found which has never introduced a formal age limit, but which in practice hires no one over age thirty-eight. This company claims that older persons have been tried but have been found to be unable to perform their tasks.

Actual restriction of opportunities for employment, therefore, cannot be measured by a company's formal statement of such restrictions. What is needed is a complete study of the age distribution of employees at various periods and a study of the actual ages of those employed and those leaving the service of a large number of companies.

Some clue to the situation is discovered, however, by analysis of the age and occupation data in the decennial censuses, together with certain other data on age distribution which have been collected by Industrial Relations Counselors, Inc. Certain other recent observations are also useful. These data, though fragmentary, constitute an attempt at direct approach to the problem of unemployment among older workers.

Age Distribution of the Gainfully Occupied 1870 to 1920. Data as to the age of persons gainfully occupied were first obtained by the census of 1870. The summary of age classifications for 1870 and 1880 differ from those used since that time, and in 1910 all persons above forty-five were grouped together. Moreover, the industrial classifications themselves have been changed, certain occupations being included in one division in one census and in another classification in another census. Only a partial regrouping of the occupations has been attempted by Industrial Relations Counselors, Inc.,

since the primary object of the survey has been a study of pensions, not a study of age distribution.

Without going into detail, the following may be observed:¹

1. Between 1870 and 1880 a notable increase in the labor of children was reported (which may have been due to the defective enumeration in the South in 1870) and a slight increase in the oldest age group, that of sixty and over, relative both to the age group in the population and the number of gainfully occupied persons.

2. In 1890 the classification of children was different from that of any other census and cannot be used for comparative purposes. Comparing 1880 and 1900, there were fewer children employed as compared with the total number of those gainfully occupied, but more as compared with the total number of children. Between 1900 and 1920, there was an enormous decline in the employment of children.

3. The change in the date of the census from June 1 in 1900 (and in the several preceding) to Jan. 1 in the 1920 census, may have helped to exaggerate the reported decrease in child labor, because of the fact that on Jan. 1 many children were in school who on June 1 might have had jobs.

4. Between 1890 and 1900 the proportion of persons employed between forty-five and sixty-four increased by about 1 per cent; by 1920 the proportion was about 4 per cent above 1900. The gainfully occupied belonging to the age group sixty-five and over fell from 4.4 per cent of the total gainfully occupied in 1890 to 4.1 per cent in 1900 and 1920, while at the same time those of the total population 65 and over who were gainfully occupied dropped from 42 per cent in 1890 to 39 per cent in 1900 and 34 per cent in 1920.

The factor of sex should not be overlooked in studying the ages of those gainfully employed. The relative number of persons between forty-five and sixty-four reported as gainfully occupied increased about 5 per cent in the thirty-year period 1890 to 1920 (the only period for which federal census data so classified are available). For men alone, however, the proportion declined about 1.5 per cent; while the proportion for women increased over 35 per cent. The proportion of those sixty-five and over, reported as gainfully occupied, declined 18 per cent in the same period; about 19 per cent for men and 3.6 per cent for women.

This decline in the gainful occupation of men forty-five to sixty-four between 1890 and 1920 can be accounted for entirely by the decline in agriculture. The number of men of these ages in agriculture, relative to the total in the same age groups fell by 31 per cent in the thirty-year period. In the manufacturing, mining, and mechanical industries, on the other hand, there was an increase of 15 per cent, and a rise of 29 per cent in all other occupations. The employment of women forty-five to sixty-four fell more in agriculture than did the employment of men, and rose more sharply in the other occupations.

Substantially similar observations hold true for the group age sixty-five and over. The decline in the proportion of those reported as gainfully employed

¹ Tables on which these statements are based are given in this paper printed as *Personnel Series, No. 3*, American Management Association.

may be accounted for mainly by the relatively dwindling agricultural population. The manufacturing, mining and mechanical industries took as large a share of the men over sixty-five in 1920 as in 1890, and increased the proportion of women by over 22 per cent. In the occupations other than these four groups—agriculture, manufacturing, mining and mechanical—the proportion of both men and women gainfully occupied increased—19 and 21 per cent respectively.

The census data indicate on the whole a decline in the employment of persons sixty-five and over; and an increase in the employment of persons forty-five to sixty-four. The decline can be accounted for wholly by migration from farms; the increase by the fact that this same migration is more than offset by the increase of women gainfully occupied and by increases in occupations other than agriculture.

While the weight of the census evidence, therefore, is that the amount of permanent unemployment among older workers outside of agriculture did not increase prior to 1920, but rather the reverse, it is to be remembered that in no census has there been any complete check-up of unemployment. There seems, however, to be no reason why the error introduced by this failure should be greater in one census than another.

The 1920 census is now ten years old. We know that there have been unprecedented shifts in industry since that time. What has been the effect on the ages of those gainfully employed? The question cannot be answered directly, but there is some significant evidence.

Age Distributions in Industrial Companies, 1911 and 1929. In order to ascertain what has occurred in the past decade, Industrial Relations Counselors, Inc., has begun the collection from a number of large corporations of data as to the age distribution of employees in 1929. The census age classifications are such that it is impossible to make divisions for single industries within the broad groups.¹

In searching for data with which to compare the present distributions, we discovered that in 1911 a congressional committee on immigration, in the course of an investigation, had made analyses of the ages of employees in certain industries. These analyses were mainly concerned with wage earners and were classified by industry. While comparisons of 1929 and 1911 will not show what has happened from 1920 to 1930, nevertheless certain tendencies may appear.

Returns which we believe to be adequate samples have been received for 1929 from three industries—iron and steel, oil refining, and slaughtering and meat packing. Data were received also from several firms in the agricultural implements and bituminous coal mining industries which are indicative of age distributions in those industries, but which we hope to supplement.

In the iron and steel industry, the relative proportion of those employed whose age at the time of the investigation was below forty-five declined as between 1911 and 1929; the agricultural implements and bituminous coal mining industries employed relatively fewer thirty-five and under; oil refining

¹ The New York State Commission on Old Age Security will attempt an exhaustive investigation in this field.

fewer thirty and under; and slaughtering and meat packing fewer twenty-five and under. Though different in the age of incidence and degree of change, all five industries employed relatively more persons over forty-five in 1929 than in 1911. All five industries employed proportionately more between forty-five and sixty-four, while three out of the five employed relatively more persons sixty-five and over in 1929 than in 1911 (Table I).

TABLE I.—PERCENTAGE DISTRIBUTION OF EMPLOYEES BY AGE GROUPS AND RELATIVE CHANGES, 1911 AND 1929

Age group	Agricultural implements		Bituminous coal mining		Iron and steel manufacturing		Oil refining		Slaughtering and meat packing	
	1911	1929	1911	1929	1911	1929	1911	1929	1911	1929
Under 20.....	9.0	5.0	10.3	4.8	9.7	0.8	12.4	3.6
20 and under 25.....	18.9	13.6	18.3	16.8	18.9	7.9	20.9	15.5
25 and under 30.....	18.7	14.0	19.1	16.4	86.7	75.5	16.9	15.9	18.6	19.5
30 and under 35.....	13.6	11.5	15.9	15.2	14.2	19.1	13.2	17.2
35 and under 45.....	20.9	30.6	21.7	26.7	23.4	32.7	18.8	26.9
45 and under 55.....	13.1	16.9	10.6	14.2	9.5	15.3	12.4	16.5	11.2	12.0
55 and under 65.....	4.7	6.8	3.5	4.9	3.1	7.5	3.7	6.4	4.0	4.5
65 and over.....	1.1	1.6	.6	1.0	.7	1.7	.8	.7	.9	.8
Total.....	100.0	100.0	100.0	100.0	100.0	100.0	100.0	100.0	100.0	100.0

CHANGE IN PROPORTIONS

Under 20.....	-44.4	-53.4	-91.8	-71.0
20 and under 25.....	-28.0	- 8.3	-58.3	-25.7
25 and under 30.....	-25.2	-14.1	- 12.9	- 5.8	+ 4.8
30 and under 35.....	-15.2	- 4.3	+34.6	+30.2
35 and under 45.....	+46.5	+23.6	+39.5	+42.9
45 and under 55.....	+29.0	+33.9	+ 60.9	+33.0	+ 7.2
55 and under 65.....	+44.8	+39.9	+141.8	+72.8	+12.5
65 and over.....	+45.4	+66.7	+143.0	-12.5	-11.1

The extent of these increases is striking. The change in the proportion of persons forty-five to fifty-four employed was as follows:

	Per cent
Agricultural implements.....	+ 29
Bituminous, coal mining.....	+ 34
Iron and steel.....	+ 61
Oil refining.....	+ 33
Slaughtering and meat packing.....	+ 7

and for persons fifty-five to sixty-four:

	Per cent
Agricultural implements.....	+ 45
Bituminous coal mining.....	+ 40
Iron and steel.....	+142
Oil refining.....	+ 73
Slaughtering and meat packing.....	+ 13

In agricultural implements, the proportion of employees 65 and over increased 45 per cent; in the steel industry, 143 per cent; in bituminous coal mining, 67 per cent. In the other two industries the proportions declined 13 per cent in oil refining and 11 per cent in meat packing. The companies in three industries making returns, agricultural implements, oil refining, and slaughtering and meat packing, maintain pension plans providing for retirement, usually at the option of the employee, at sixty and sixty-five. This might partially account for the decline in the proportion of persons sixty-five and over in the latter two industries.

Despite the increase in these industries, it ought to be observed that the proportion of employed persons sixty-five and over in these industries is much less than the proportion of persons of the same age to the population ten years of age and over. The proportion of those employed between forty-five and sixty-four is greater than for the population over ten. Both comparisons are rendered somewhat inaccurate by the fact that few persons under sixteen or seventeen are employed in any of these five industries.

Some idea of the situation in companies for which no comparisons can be made may be gained from data concerning retirements on pension. On the railroads, for example, the number of persons retired has increased very rapidly for many years, and the growth of the pension rolls gives no indication of cessation. Moreover, employment on railroads has been declining. Data on the average age of all persons retired show no great movement in either direction. It seems to be true, therefore, that the age distribution of railroad employees is steadily tending upward. This in general is the experience of all companies maintaining pension plans.

While the average age of all employees retired under pension plans for which data were available, has not changed materially over the past twenty years, nevertheless there does seem to have been a definite change in the ages at which persons were retired for disability and the ages at which they were retired for superannuation. On the whole, the average age of persons retired for superannuation has increased slightly, while persons becoming disabled, seem to be somewhat younger. Moreover, on the railroads, in the steel mills, and in certain other industries as electrical apparatus and transportation equipment, the number of persons retired on account of disability is increasing more rapidly than retirement for superannuation. In this connection it is to be remarked that disability rates in industry are higher than rates for permanent and total disability used generally by insurance companies in connection with life or group policies. The difference is accounted for by permanent and total disability for specific occupations or groups of related occupations. Such permanent and total disability as comes within the service requirements of pension plans seems to be increasing.

The evidence is confused somewhat by reason of changes in the requirements for receipt of pension and by possible changes in administration, many of which are necessarily unknown to persons on the outside. It is known, however, that the constantly mounting expenditures under pension plans have forced companies recently to postpone retirement of persons who might have received pensions earlier under former conditions. On the other hand, a number of companies have made studies of payroll relief with reference to maintenance of a pension plan and have become convinced that prompt retirement of inefficient persons effected considerable economies. They have been less concerned with the gross expenditures for pensions than with net savings.

Finally, the limitation of immigration will probably tend to cause an upward movement in the age distribution more rapid than would have occurred had immigration been at pre-war levels. It is impossible to say just how much change will be attributable to this cause. The influence will be felt mainly in the East, and naturally the large industrial cities will be more affected than will other sections and smaller centers.

Most of this refers to persons who are actually at work. What of the elderly man unemployed? One may doubt, in the first place, if it is possible to make any general statement. There are nevertheless some few indications that statements concerning the inability of persons forty-five years of age and over to obtain employment have been exaggerated.

At a meeting of the Eastern Massachusetts Section of the Taylor Society in Boston, held in April, 1929, the Director of Statistics, Department of Labor and Industries, Commonwealth of Massachusetts, presented records dealing with the placement of men and women applicants for employment at four Massachusetts public employment offices in 1928. The male applicants (15,453) were divided into six age groups. The following were the percentages of each group actually placed in employment:

	Per cent
Under 25.....	55.1
25 to 34.....	55.3
35 to 44.....	54.7
45 to 54.....	59.5
55 to 64.....	42.9
65 and over.....	28.6

These data indicate no discrimination prior to age fifty-five. A finer age classification might well reveal an even older age. But even so, the person fifty-five to sixty-four has apparently on the average over three-fourths as much chance of obtaining a job in Boston, Springfield, or Worcester as a man under thirty-five. The average, however, does not reveal the whole story.

At the Springfield and Worcester offices where many of the applicants for employment seek positions in the metal industries, a larger proportion of those under forty-five years of age were placed than of those forty-five years of age and over, but at the main office in Boston where there is a greater diver-

sification of industries the reverse is true. At the mercantile office in Boston, however, a much larger percentage of male applicants for clerical and office positions under forty-five years of age are placed than of those forty-five years of age and over.¹

This seems to indicate that such discrimination as there is is inherent in the job and not due to extraneous circumstances. Whether any older applicants were rejected purely by reason of age is not stated.

Women applicants were divided into two age groups only—over and under thirty-five. A considerably larger proportion of those over thirty-five were placed than under thirty-five. This seems to be accounted for by the fact that most of the women were placed in domestic employment. In stores and offices, there was a marked discrimination against women over thirty-five.

On the whole, a general statement of the facts concerning age limits in industry might be made somewhat as follows: *The introduction of machines, the whole process of mechanization in industry, has always caused displacement of a certain amount of labor. Complaints on this score indicate that whenever such changes occur, older persons have had more difficulty possibly in obtaining new jobs than younger ones, irrespective of whether maximum age hiring limits were imposed by employers.*

Why, therefore, have hiring age limits been resorted to? In the first place, it is unlikely that imposition of hiring age limits has been very closely connected with the inauguration of employee welfare schemes. The data which are available indicate that age limits are about as prevalent in companies which do not as those which do have various types of benefit schemes. Moreover, in many, if not in the majority of cases, the limit antedates the benefit scheme. So far as pensions are concerned, expenditures, though growing rapidly, are generally less than one per cent of payroll and so far probably are almost altogether offset by economies realized through the retirement of inefficient employees. In the case of group life insurance, the costs are quite low on the whole and possibly the economies are not so apparent. Nevertheless, it seems to be extremely doubtful that group life insurance has had any great part to play in the imposition of hiring age limits for new employees. It is quite true that the costs for older employees in both pensions and life insurance are several times the cost for younger employees, but the total cost in relation to payroll and possible savings by elimination of the relatively few older men, who would in any case be engaged, would result in relatively small economies. Some twenty years ago when insurance was being handled almost exclusively through mutual benefit associations, the members of these associations ordinarily refused admission to persons over certain ages—thirty-five, forty-five, or fifty. These restrictions do not appear to have been taken over by the companies themselves. So far as workmen's compensation is concerned, the situation is more doubtful. One suspects that even if the costs for old men are higher than for younger, the employers

¹ The quotation and the other data concerning the records of Massachusetts public employment offices taken from "Employment Age Limitations," *Bulletin of the Taylor Society*, vol. 14, No. 5, pp. 223-8, 1929.

do not know it. All these costs could be kept down by laying off men over a certain age, but any such blanket policy would be suicidal. Talk of general firing age limits for employees above certain ages in any industry is sheer myth. While it is true that within corporations there is considerable readjustment in the tasks of men as they grow older, cases of wholesale lay-offs of men above any specified age are exceedingly rare.

Hiring age limits, as has been pointed out, have occurred largely in the plants of greatest size. Such organizations are those which have usually established a centralized employment department. These employment departments in many cases have attempted to control rigidly the hiring policies of the corporations and the age limit at hiring has in many cases been an incident to such control. Among the things which a good employment department tries to do is to translate the feeling of responsibility of the particular company for its men of longer service into terms of jobs within the organization. In order to do this, it necessarily excludes from a number of positions which can be filled by older men, persons from outside the organization. If this were not done, and a decentralized employment policy were followed, the task of adjusting the work to the capabilities of the older men would be vastly more difficult and probably in many cases would be rendered entirely fruitless.

Briefly, hiring age limits are the rule in railroads and in public utilities. They are still the exception rather than the rule in manufacturing companies. Their existence, as well as the failure to employ older men in the absence of a formal policy, is due to:

1. The demands of certain jobs which employees not in their prime cannot meet; that is, permanent and total occupational disability.
2. The demands of public safety on railroads.
3. Seniority rules on railroads.
4. In certain large public utilities the necessity for training for life jobs in a unique type of work.
5. The saving of jobs capable of being filled by older workers for employees of long service.

The evidence presented in this paper points to the first as by far the most important cause.

Recent Complaints against Hiring Age Limits. The explanation of the unusual volume of complaints as to hiring age limits in the last few years probably lies in the decline in employment in manufacturing industries, despite prosperity, and the downward trend in employment on railroads. Prior to 1922, declines in employment in all the large industrial groups occurred only at the time of depression when men, young and old, were affected together, and once the cycle turned upward employment ordinarily was not hard to find. In the last seven-year period, however, the constant shrinkage in employment has necessitated a shift in the occupation of many of those who seek new jobs. It was entirely natural that this condition, coupled with change in technique and more mechanization, should fall heavily upon the older man. *Nevertheless, the data of five industries indicate*

that the changing processes and industrial shifts have fallen even more heavily upon younger men. This probably would be true whether or not hiring age limits are commonly established. Moreover, the implication of the facts presented here is that had such a condition occurred at any time in the last thirty years, the effect on the older man would have been precisely the same. It is quite probable that the existence of hiring age limits would have been blamed for the situation.

If the statement of facts and their interpretation have been correct, it is possible to say that the abolition of age limits for hiring would not materially change the situation since the existence of age limits derives from the nature of jobs to be performed. It must also be said that the passage of a state old age pension law, modeled along the lines of those in the ten states which now have them, will afford little, if any, remedy for this situation. While they may in a few cases assist older workers to obtain employment by reason of relieving a prospective employer from the fear of a possible future burden, nevertheless they will do nothing to change the nature of the jobs which these older men will be called upon to fill.

It seems safe to conclude, therefore, that the real problem is not the adoption of hiring age limits, nor of arbitrary discrimination against the man over forty-five, but rather permanent and total occupational disability. There are a number of ways by which this problem might be met. The only two devices for meeting it in wide use today have been developed by industry itself. The first of these agencies is the industrial pension plans, a majority of which pay pensions for permanent and total disability, a definition which for them includes occupational disability as well as general. Group life insurance policies provide for payments for permanent and total disability, but the definition of such disability is narrower than under pension plans. Workmen's compensation takes care of much disability, but not of the sort here under discussion. The second agency for meeting of the problem of the worker who is not able to meet the changed conditions of his job, lies in the personnel programs of many American corporations. Even though the worker himself be unable to meet the new requirements without assistance, careful and patient training in many cases would fit him for the task. Such training many companies attempt to give him. If the disability cannot be removed by training, there can be a transfer to another job; or if no place is open, and the requirements have been met, a pension may be granted.

These agencies are not perfect. The pension plans by reason of their long service requirements to provide for many disabled employees, though new pension plans are much more liberal than the older ones. Both kinds of programs are as yet adopted by only a minority of companies. There is an imperative need for much broader and more far-reaching agencies, possibly modeled along the existing schemes, but more liberal, possibly of a different type altogether.

It should not be forgotten, moreover, that while this whole problem is serious, it does not seem to be getting worse, so far as the occupations outside of agriculture are concerned; but rather better. The factors tending to make possible the greater utilization of older workers in industry seem to have the upper hand.

INDUSTRIAL PENSION PLANS

BY EDWARD S. COWDRICK

Preliminary Decisions of Management. The industrial manager who is considering the adoption of a pension plan or the revision of an existing plan should first of all reach decisions on the following questions:

1. Shall the company have any pension plan?
2. Shall the pension be contributory or non-contributory, and what shall be the extent of the benefits?
3. What shall be the principal terms of the plan?
4. What will be the immediate and ultimate cost of pensions and how shall this cost be met?

Nature and Purposes of Pensions. In determining whether or not a company should pay pensions to superannuated employees it is wise to consider first the nature of industrial pensions and the reasons by which, if at all, their payment can be justified. Lack of clear thinking on these points has accounted for much distorted reasoning on the whole pension question.

Pension Problem of Recent Origin. The industrial pension problem is distinctly a product of modern conditions. Of the pension plans in effect in the United States, only a handful were in existence before 1900. It appears that until recent years the relief of old age, even in industrial countries, was mainly a part of the general problem of poverty. Laborers in general had little more than the means for bare subsistence, and if the destitution of the aged worker was more abject than that of his sons or his grandsons, the difference was in degree rather than in kind. Workingmen were expected to earn their own bread throughout practically their entire adult lives. Those who through any misfortune failed to do this were normally supported by children or other relatives, with the poorhouse as a last refuge.

Twentieth century industry has radically altered this condition. For one thing, the expectancy of life has risen, with a corresponding increase in the number of workers who reach or pass middle age. But as the years of life have increased, the proportion of those years available for earning a livelihood has declined. The working period has been lopped off at both ends. The spread of education and the decline of child labor are sending workers into industry at higher ages than in the past, while at the same time there is proportionately less employment for the laborer who has grown old or has even come to later middle life. The worker who has passed middle age may not actually be dropped from his employer's pay roll; probably he will not be dropped so long as he is able to perform his task with an acceptable degree of efficiency, but once out of employment, for whatever reason, he finds that jobs are scarce. For reasons which need not be discussed here, an increasing number of employers prefer not to take on new employees at ages beyond forty or forty-five.

Other Hazards of Age. While this process of shortening the working period has been going on the laborer has suffered loss in respect to at least one

of his sources of support in old age: the support from his children. The laborer of today is likely to marry late, in comparison with the customs of his ancestors, and to have relatively few children. These children, marrying late in their turn, may be expected to be in the midst of rearing their own families just at the time when their parents are in need of aid. The margin of income available for the support of the passing generation is usually small. It is true that these disadvantages are offset partially, perhaps in many cases wholly, by the greater prosperity of the working classes. But this increased prosperity, except in unusual cases of thrift, works to the advantage of the man whose earning power is unimpaired, rather than to that of the retired laborer.

The need for organized maintenance of the aged probably has been increased also by the conditions of modern American life under which proportionately larger numbers of the population are wage earners and renters, and proportionately smaller numbers are farmers, small shopkeepers and home owners. In an earlier agricultural period the aging farmer was likely to find both a home and a livelihood in the land which he had acquired and improved during his more active years, while his sons, not yet come into their expected inheritance, often were content to contribute their labor to the family's support. Likewise the average shopkeeper with a home at or near his place of business could carry on with the help of his family long after the age at which he would be acceptable as an employed workman.

An industrial era has brought radical changes in all these conditions, at least in their effect upon a large portion of the population. Wage earners have been attracted to large cities or crowded industrial centers, where housing problems are acute and the cost of real estate makes home ownership difficult for the average workingman. To an increasing degree the family income is dependent upon one breadwinner. As long as this breadwinner is employed at good wages the family is likely to live on a scale of comfort far superior to that afforded in an earlier and simpler era, but if he falls ill or by reason of age or other cause is unable to get work, the economic plight of the household is likely soon to become desperate.

Corporations Are Older. Another element that has profoundly affected the need for support in old age, in so far as it relates to industrial employees, is the increasing age of industrial organizations, themselves. A company in its first twenty to twenty-five years is likely to have no pension problem at all unless it has hired men already past middle life. Up to the beginning of the twentieth century most of the large industrial corporations were of comparatively recent growth. Many of them are still in that condition. An increasing number, however, have been in operation continuously for forty or fifty or more years and have accumulated a relatively large number of pensioners and of employees approaching retirement age.

For all these reasons the need for organized support of workers in old age has become increasingly urgent. At the same time the growing wealth of the country has pointed to the possibility of meeting this need more liberally than could have been done in the past. Pensions, public and private, have grown in numbers and in the importance of their contribution to social and industrial economy.

What Is an Industrial Pension? Among the theories that have been advanced by those who have sought to classify industrial pensions are the following:

1. A pension is a deferred wage.
2. A pension is a charity or gratuity; and therefore, according to some arguments, an improper expenditure of company funds.
3. A pension is payment for continuity of employment, as distinct from actual services for which compensation was paid currently.
4. A pension is a deserved reward for long and faithful service.

By present day thinkers, some of these theories have been discarded, while others have been relegated to minor positions. It is now generally conceded that a pension is not a "deferred wage"—or any other kind of a wage. Nobody "earns" a pension. Furthermore, a pension is not—or should not be—primarily a benevolence; it scarcely could be justified on charitable grounds. The theory that a pension constitutes payment for continuity or something else not currently compensated has little weight except possibly in the thought that it provides a legal justification for something that might otherwise be an unwarranted gratuity. Neither is a pension, to any considerable degree, a reward for service; one would be hard put to it to defend the payment of money merely for longevity.

What, then, is the nature of an industrial pension?

First, it is a part of the employer's personnel program, the aggregate result of which is expected to be improved efficiency and morale among the working force. In this program the pension is of importance mainly because, through lessening the dread of poverty in old age, it helps to rid the worker's mind of worry over the future. A pension also probably has some effect in reducing labor turnover. To whatever extent it increases contentment and promotes friendly feelings between employees and management, a pension contributes directly to efficiency.

More important than all, and constituting the main justification for an industrial pension, is the service it renders in furnishing a means by which superannuated employees may be removed from the active pay roll without offense either to the conscience of the employer or to the opinions of other employees or of the public. In the lack of a pension plan, management—management of a large or conspicuous corporation at any rate—is likely to retain workers on the active pay roll long after they have passed their periods of usefulness. This policy, it is generally admitted, usually is more costly than any reasonable expenditure for pensions.

Basis for Decision. It is by keeping in mind the nature and purposes of industrial pensions that the management of a business organization can best determine whether or not a pension plan should be adopted. Recognition of the advancing age of the working force and of the prospective, if not already existent, superannuation of some of the employees, leads logically to the conclusion that the cost of old age will have to be paid in some way by the company, whether or not it maintains a regular pension plan. Few managers are willing to throw out aged employees to be supported by the public. Under typical conditions the choice lies between pensioning aged workers,

formally or informally, and retaining them on the active pay roll at such jobs as they are able to do. Present day industrial thought inclines toward the pension alternative.

Contributory and Non-contributory Pensions. A non-contributory pension is one in which all the expense is borne by the employer. A contributory pension is one in which employees themselves pay a part of the cost. In some contributory plans the payments of the employer and of the employees go into a single fund out of which all annuities are paid. A more recent and in most respects a preferable procedure is to administer the company fund and the employees' fund separately, with a minimum allowance from the company supplemented by pensions paid for by the workers. Either a contributory or a non-contributory pension may be paid in the form of annuities purchases from an insurance company.

Arguments for Contributory Pensions. Until recently the weight of industrial opinion has been strongly on the side of pensions paid for and controlled by the employer. Even yet a large majority of industrial pensions are of the non-contributory type. Recent years, however, have seen a tendency in the direction of contributory pensions. It is yet too early to predict how far this tendency will go.

On the side of the contributory pension there are impressive arguments. In the first place, if it is reinsured, or if obligations are covered by a sufficient reserve fund definitely set aside, it is practically certain to be paid, since it is not dependent upon the whim of the employer nor even upon the permanency or solvency of the business. To be sure, even under a contributory plan the employer usually can terminate his own payments into the fund.

The contributory pension relieves the employer of a part of the expense, and at the same time encourages self-dependence among the employees by putting upon them a part of the responsibility for their own future support. When the contributory pension takes the form of insured annuities, the company is relieved of the necessity of maintaining a large cash reserve for the payment of pensions and, at the same time, by following a pay-as-you-go policy, the employer avoids the danger of incurring future obligations of unknown amount.

Contributions from employees can be graded upward with the age at which an individual enters the service, and thus an employee taken on at mature age can be required to make provision for his own support after retirement. A provision of this kind makes it easier for a company to dispense with maximum age limits for hiring.

Arguments against Contributory Pensions. Against these arguments in favor of contributory pensions there are practical considerations which thus far have limited the adoption of this form of retirement plan. A contributory pension plan, of the type in which the money of employer and of employees goes into a common fund, involves contractual rights. With the first dollar contributed by employees the employer loses his privilege of paying or withholding pensions as he will; he is dealing with money that is not his own. The cautious manager hesitates to incur this contractual obligation, especially since it carries with it the practical necessity either to reinsure the pensions or to take money out of the business for the maintenance of a reserve adequate

for future incurred liabilities. True, he ordinarily does not expect to withhold pensions—sometimes he is not so very sure that he could do this lawfully even under a non-contributory plan—but he has an instinctive reluctance to enter upon a definitely enforceable agreement.

The industrialist believes that a contributory pension plan, to be effective, should be participated in by all employees. Otherwise the very ones who were most in need of protection would reach old age with no provision for their support, and the problem of superannuation would remain unsolved. Many managers consider that universal participation in a contributory plan would involve compulsion, and they hesitate to require contributions from manual workers.

Still another objection concerns the element of cost. A contributory pension, with its contractual obligations, involves the absolute safeguarding of pension rights. This seemingly can be done in one of two, and only two, ways: by setting up reserves, outside the business of the employer, which are actuarially sufficient to make the plan solvent, or by reinsurance. Either alternative involves the investment of large sums at low rates of interest—presumably far below the return which the employer would expect the same sums to earn in his own business. Over a long period of years this difference in the earning power of money might become a factor of much importance.

Extent of Pension Benefits. Decision between contributory and non-contributory pensions, and determination of the appropriate magnitude of annuities, may be facilitated by recalling the purposes for which pensions are paid. Since the primary reason for superannuation retirement is to increase the efficiency and the profits of the business by removing aged employees from the active pay roll, the employer should bear the expense up to the point at which this purpose is accomplished. Beyond this point old-age support, if furnished within the industry at all, should be looked upon as a responsibility of the employee himself. This means that the employer, if he chooses to retire aged employees, should provide at his own expense annuities which will permit of their retirement on terms conforming to business ethics and approved by public opinion. More than this he should not pay, since then he would be giving away stockholders' money without benefit to its owners and without moral obligation to do so.

Determination of the exact amounts that meet the requirements just stated, in a particular company or for individual beneficiaries, is more difficult than is the formulation of the general principle. Ordinarily the employer should be guided by cost of living in the community and by standards established by pension plans in general, including those of other companies, with whatever aid is furnished by his own sense of fairness and his own understanding of the needs of retired workers. It should be remembered, however, that the standards established by industrial practice, and enforced by public opinion, are subject to change. At present an annuity equivalent to 1 per cent of final annual earnings, multiplied by the employees' years of service, is generally approved as adequate, especially if there is an established minimum which represents the requirements for existence. If the pension is based upon total earnings rather than upon final earnings, the percentage

presumably should be increased. Some time in the future this standard may be raised, through the advancing public recognition of the employer's obligation to his worn-out workers; or, conceivably, it may be lowered, if the cost of living is further reduced or if pension expense becomes an excessive charge upon industry.

Shall the Employee Also Pay? Whatever may be the exact method of computing the annuity, one thing is certain: the ordinary non-contributory pension under present day industrial conditions will not be adequate for a comfortable living in the case of the lower-paid employees. Some employers whose plans are fully approved by public opinion frankly admit that they are paying "poorhouse pensions"—nothing more. It is highly desirable therefore that employees be encouraged to provide supplementary income for their own old age. This income may be furnished through contributory pensions, through insured annuities, or through savings plans. Payments of employees toward retirement funds, if possible, should be substantial enough to insure incomes which when added to the pensions paid by the employer will provide adequate support for the beneficiaries and their dependents. At the same time workers should not be encouraged to save to an extent that will cause them to neglect their families or seriously cut down their standards of living. Except for the lowest paid workers and those suffering unusual hardships in the way of illness or unemployment, it should be possible to fulfil both these requirements.

Along with the pension paid for by the employer, therefore, may properly go a supplementary plan financed by contributions of the employees. This plan may take the form of insured annuities, or of any of the other types of contributory pension available for an industrial group. Somewhat the same purpose may be secured by a savings plan, a stock plan, or an investment trust, provided that the safety of principal is sufficiently safeguarded and that at least a considerable portion of an employee's deposits are retained until he reaches retirement age or leaves the service of the company.

Participation in the supplementary plan may be either compulsory or voluntary; there are good precedents for each method. When the employer pays a pension sufficient to warrant retirement, however, the compulsory provision seems less important than in the old type of contributory pension plan in which the worker either participated or received no pension at all. In some states there is doubt as to the legality of enforced contributions from wages. Some companies encourage participation in the supplementary plan by increasing the non-contributory annuities to those who provide retirement income for themselves.

Terms of Pension Plans. Having decided whether the pension shall be contributory or non-contributory, the company next faces the task of settling upon the other terms of the agreement and drawing up the detailed retirement plan. Here much aid is available from plans of other companies, some of which furnish precedents for almost any arrangement the manager may have in mind. It is wise to study a rather wide range of existing plans and if possible to secure information bearing upon the experiences of the sponsoring companies in administering them. The manager may also find it advisable to call in expert help, from within or without his organisation, before com-

mitting the company to a particular form of pension plan. A pension is a long time arrangement and mistakes once made are difficult to correct.

Detailed discussion of all the terms of a pension plan is beyond the scope of this chapter. Only a few of the most important points will here be covered.

Age and Service Requirements. Pension plans ordinarily provide for retirement, either voluntary or compulsory, at a fixed age and after a specified term of service. The age is usually sixty-five or seventy years and the term of service is seldom less than twenty years. Some plans provide that retirement shall be optional, on the initiative of the company, of the employee or of either, at the age of sixty-five, and that it shall be mandatory at seventy. Frequently a lower retirement age is prescribed for women than for men.

In a simple non-contributory pension it seems reasonable to set a high age for automatic retirement, or none at all, and to give the company a large measure of control over optional retirement at lower ages. Since the company is paying the entire cost of pensions, it is justified, within reasonable limits, in retaining a man in active service after he has passed the minimum retirement age or in retiring him at the earliest possible date, depending upon the value of his services. Few employees wish to retire on pensions as long as they can retain their full wages, and the company is not likely to be criticized for holding men on the active pay roll beyond the time at which they might be retired. In this as in everything else connected with pensions, however, absolute frankness and scrupulous fulfillment of all obligations is essential. If the terms of the plan permit a man to retire at a certain age and he wishes to do so, it is obvious that he should not be compelled to remain in the service.

If the pension plan is a contributory one, the employee's right to retire, or at any rate to begin drawing his annuity, when he has fulfilled the prescribed conditions, should be inviolate.

Usually the pension is graded in accordance with length of service. This policy probably is in part a survival of the old notion that a pension was "earned." Whatever its origin, the practice of basing pensions upon length of service has sound justification in public opinion, which rightly or wrongly is reluctant to sanction equal awards to a man who has spent forty years in his employer's business and to one who has barely completed the pension requirement of twenty or twenty-five years.

Credit for Past Services. Much variation in policy exists as to giving credit for former service when an employee who has once left the company returns to its rolls. Some pension plans give credit for total service regardless of the number or the duration of breaks; others consider only the last continuous period of service, while in still others service breaks of limited duration are permitted. There are arguments for and against all three of these practices. Probably the preferable method is to permit breaks in service for reasonable periods (for example, eighteen months or two years) and to require an employee rehired after a longer absence to begin building up his pension credits over again.

Perplexing problems sometimes arise in computing pension credits of employees of plants or companies taken over by or merged with a corporation

that has a pension plan. Some companies in this situation allow no credit for services rendered to a predecessor concern, holding that the service of employees for pension purposes begins at the time the unit was acquired. Others allow full credit for service in the acquired plant or company. Still others attempt various compromises, sometimes on the basis of persuading the former employer to assume some or all of the pension obligation.

Probably no invariable rule can be laid down to cover these cases. It should be remembered, however, that employees of acquired properties will in time reach ages when their continued employment will be unprofitable, and that it will then be to the advantage of the existing management to place them on the retirement list. If no provision for annuities has been made, the employer will not escape public criticism simply because sometime in the past the men worked for a former owner of the plant.

Pensions for Disability. Many plans, in addition to retirement at a fixed age and after a definite term of service, provide for earlier retirement if the employee becomes physically or mentally incapacitated for his work. Terms of pension plans in this respect show wide variations and there is little agreement either as to the degree of disability or as to the minimum length of service that will render an employee eligible to a pension. In the present status of pension finance it is probably safer not to put disabled employees on the pension roll until after considerable service coupled with a reasonably mature age, (for example, fifteen years' service and fifty years of age), and to take care of other disability cases through mutual benefit associations, group disability insurance, or in some other way. The term "disability" should be interpreted somewhat strictly and not stretched to cover ordinary inefficiency.

Prorated Pensions. Some companies have experimented with reduced pensions for employees who have to be retired within a few years of qualifying in point of age and service. If a man is retired at sixty-two, for example, when the regular retirement age is sixty-five, he may be paid a pension based upon his attained age and service, but prorated over his longer life expectancy. A provision of this kind is especially useful when a company finds it necessary to shut down a plant and thus release long service employees.

If provision for prorated pensions is included in the plan, however, its application should be limited to employees who are comparatively close to the age and service requirements for regular pensions. Younger employees or those of less service, if necessarily laid off, can better be indemnified through dismissal compensation.

Awards Based upon Earnings. Nearly always pension payments bear a relationship not only to length of service but to the earnings of the individual during his active years. The variation in accordance with earnings is based upon standards of living. The physical needs of a common laborer and of a vice president may be much the same; it may take as much food to nourish one as the other, but in terms of practical possibility their living requirements are vastly different. An attempt to pension high salaried officers upon allowances suitable to the needs of laborers will simply mean that in many cases the highly paid man will not be retired at all and the pension will thus defeat its own purpose.

Maximum and Minimum Pensions. But in thus grading pensions according to past earnings, many companies have found it advantageous to set minimums below which no pension shall be allowed to fall and maximums beyond which none shall rise. The minimum is ordinarily fixed at a figure which is supposed to represent about the least upon which the retired worker can exist. Its justice and its usefulness in carrying out the purpose of a pension plan are too obvious to need defense. As to the desirability of an absolute maximum there is considerable disagreement in theory and in practice. Some companies pay no pensions exceeding \$1,200 a year; in others high officials may retire on annuities of \$50,000 or \$75,000.

Seemingly the best of the argument is on the side of the maximum, which, however, should not be set so low that it will prevent the retirement of highly-placed men when they have passed their years of usefulness. The object should be to determine a top limit which will enable a pensioned official to live in ordinary comfort. Presumably he will wish to live on a still higher scale, but for this he should have made provision during his productive years. An annuity that allows of luxurious living standards becomes actually a bonus and finds justification, if at all, on some other theory than that which underlies pensions.

A management which for reasons of policy hesitates to set a horizontal limit expressed in dollars can achieve somewhat the same result less drastically, and perhaps at the same time avoid the necessity of a fixed minimum, by adopting a graded annuity scale with the percentage basis diminishing in the higher salary ranges. For example, a pensioner might be allowed 2 per cent on his first \$1,000 of final earnings, multiplied by his years of service; 1 per cent on the second \$1,000; $\frac{1}{2}$ per cent on the next \$5,000 and $\frac{1}{4}$ per cent on all the remainder.

Final Earnings or Total Earnings. Most pensions in American industrial companies are computed on the basis of "final earnings"; that is, the wages or salary of the employee during the last five or ten years of his service. An alternative method is to figure the pension on the basis of the remuneration received by the employee during his entire active period. In favor of this method, which is in common use in England, it is argued not only that it may reduce pension disbursements (although it does not necessarily do so, since the percentage rate or other elements of the computation can be altered) but that it partially takes the place of a maximum limit, since the high salaried men usually are the ones whose earnings have increased periodically up to their time of retirement.

The principal claim for this method of computation, however, is that it facilitates actuarial estimates of pension liabilities. The actuary can figure just what liability has been incurred this year for pensions to active employees on the basis of this year's earnings; he can only guess at what the earnings will be twenty-five or thirty years in the future.

In spite of the impressive arguments in favor of the entire compensation method of computing pensions, most industrial managers incline toward the more ordinary practice of basing pensions upon final earnings and thus bringing them more nearly into line with the cost of living at the time the employee goes on the pension roll. Whatever may be the respective merits

of final compensation or total compensation as the basis of figuring pensions, the company adopting a pension plan should make a clear distinction between the two methods and understand accurately just what is involved in the choice of the one or the other.

Cost of Industrial Pensions. Most of the earlier pension plans were adopted with no definite provisions for meeting the financial obligations entailed and with no clear understanding of the future extent of pension disbursements. In recent years much attention has been given to the financial side of the pension problem.

Before adopting or revising a pension plan it is important to secure actuarial data showing as accurately as possible what will be the cost of pensions, not only in the next five or ten years, but in the next three or four decades. This preliminary estimate should be rechecked from time to time in the light of actual experience.

Methods of Meeting Obligations. With the cost of pensions once determined, the next decision involves ways of meeting the financial obligation. Six principal methods are in use. Some companies simply pay retirement allowances as a part of current operating expense, making no provision for meeting future obligations. Others "fund" the pensions already granted by setting aside sums sufficient to pay them during the expected lives of the pensioners. Sometimes a fund is set up, either when the pension plan is started or at some later period, from which the income is expected to be sufficient to pay pensions for an indefinite time. Some companies, instead of setting up a large reserve all at once, turn into the pension fund a definite percentage of the active pay roll each year, depending upon the amount thus accumulated, with interest, to carry the pension over the "peak" which is expected to be reached in the future. In other cases the company pays into the pension reserve each year a sum actuarially computed to be sufficient to cover the pension liabilities accruing during that year on account of employees on the active pay roll. The sixth method of financing pensions is through insurance, usually by some modification of the ordinary purchase of annuities.

When a pension fund is set up by the company there is a further choice between making it a "paper" reserve on the books and taking the money actually out of the business and putting the cash or securities into the hands of trustees.

Importance of Security. In the case of contributory pensions, the employer has no option but to make at least the employees' funds secure beyond all question, either through a trust agreement or through insurance. Even in non-contributory pensions the present tendency is in the direction of actual or approximate solvency. Some companies have protected non-contributory pensions by the creation of funds actuarially sufficient for accrued and accruing liabilities, while others are gradually building up their reserves with that ideal in view.

While it can scarcely be asserted that an actuarially solvent fund is an absolute essential of a non-contributory pension, the company operating or contemplating a pension plan should give much attention to the financial aspects of its obligations and should make its plan as secure as conditions warrant.

METHODS OF FINANCING PENSION PLANS

BY GILBERT E. AULT, *Associate Actuary, Woodward, Fondiller and Ryan*

The adoption of a pension plan in which all or part of the cost is borne by the employer places upon the particular industry a definite liability in the nature of an obligation to pay the benefits promised. The methods which have at one time or another been employed for financing this liability differ chiefly in accordance with the concept of what portion of the total liability has already accrued to date. They range all the way from the so-called cash disbursement method to the permanently endowed plan. The former method provides no reserve fund whatever out of which to meet the steadily increasing payments to retired employees. It recognizes no pension liability except as the payments to pensioners actually become due. It claims for itself financial solvency so long as there are sufficient funds on hand to meet these payments. The latter method attempts to finance once and for all the entire pension liability not only for existing employees but also for every employee who may enter the service throughout the future. The method claims financial solvency so long as the income from the endowment is sufficient to meet pension payments.

It is generally conceded that neither the cash disbursement method nor the permanently endowed plan are satisfactory methods of financing pension benefits, though there exists a wide divergence of opinion as to the particular intermediate method which best solves the problem. It is quite probable that there is no single best method. The method which best suits one case may not be the best method in another case. Much depends upon the financial requirements of other projects and the probable incidence of the future ability to meet the pension liability. It may well be that the needs of Company A, for example, will best be served by a method producing a cost which when expressed as a percentage of the payroll will increase slightly for a number of years. Company B, on the other hand, may be better served by a method producing a cost which will decrease for a number of years. The pension liability of Company C, however, may be best financed by a level percentage of the payroll.

Basic Precautions. Regardless of the particular method of financing adopted and regardless of whether the plan is reinsured or not, it is important to observe the following precautions:

1. Careful computations should be made to determine not only the current cost expressed as a percentage of the payroll but also the probable cost ten, twenty and thirty years hence.
2. A revaluation of the liabilities already accrued under the particular method should be made every year.
3. Every five years a detailed investigation should be made of the actual experience as regards important factors such as salary increases, rates of withdrawal from service, rates of retirement on pension and rates of mortality both during active service and subsequent to retirement.

Where pension costs for one reason or another show a distinct tendency to increase or decrease from year to year, it is of vital importance that the

employer be fully informed as to the probable future trend in the cost under the particular method adopted. The computations should involve all pertinent factors including the rate of withdrawal from service, the probable future increases in salary and the rate of retirement on pension, even though the plan be reinsured with an insurance company.

Methods of Financing. Five of the available methods of financing intermediate to the cash disbursement method and the permanently endowed plan are given in order below:

1. Financed at *retirement* on pension.
2. Financed by *single* premium group annuities.
3. Financed by *level* percentage of payroll.
4. Financed by *annual* premium group annuities.
5. Financed at *appointment* to service.

The above methods have been arranged according to the extent to which they build up a reserve fund out of which to meet the steadily increasing payments to pensioners. The first method builds up a relatively small reserve while the fifth method builds up a relatively large fund.

As regards the probable future trend in the cost, the first two methods will normally produce a cost which may be expected to *increase* steadily for a number of years, with the cost under the first method tending to increase over the longer period and reaching ultimately a higher percentage of the payroll. The last two methods, on the other hand, will normally produce a cost which may be expected to decrease steadily for a number of years, with the cost under the last method tending to decrease for the longer period of years and reaching ultimately a lower percentage of the payroll. The third method is designed primarily to produce a cost which will as nearly as possible remain a level percentage of the payroll under varying conditions of growth.

Under each of the two group annuity methods the amount of the annual pension is based on the average salary during the entire term of active service. Under the remaining three methods the annual pension may also be based on the average salary during the entire term of active service though it is more frequently based on the average salary during the last five or ten years of service or even on the final salary.

Financed at Retirement on Pension. This method recognizes no pension liability prior to the time of retirement on pension. The liability assumed at that time is the then present worth of the probable future payments to be made in respect of the particular retirement. This sum may be retained under the control of the employer or it may be turned over to an insurance company. In the latter event the mortality risk after retirement is transferred from the employer to the insurance company which undertakes to meet the pension payments as long as the retired employee may live.

This method is but little better than the cash disbursement method. Costs thereunder show a distinct tendency to increase. The pension liability for a particular group of employees is financed out of corporate earnings produced by other employees rather than out of corporate earnings produced by their own services.

Financed by Single Premium Group Annuities. This method is usually associated with a pension plan which is reinsured with an insurance company, though it was adopted by a large self-administered plan without the reinsurance feature. The usual single premium group annuity contract provides that the employees make contributions which are expressed as a level percentage of the salary. These contributions are applied each year at the employee's attained age to purchase single premium deferred annuities. The employer then purchases for each employee additional single premium deferred annuities in sufficient amounts to make the total deferred annuity purchased each year equal to a fixed percentage of the employee's salary for that year. The method is predicated on the following reasoning:

1. That the liability incurred during each year of service is the single payment required to provide for the pension earned during that year.

2. That since the pension is expressed as a percentage of the average annual salary during the entire term of service multiplied by the number of years of service, the pension earned during each year is that same percentage of each year's salary.

3. That even though the pension costs for individual employees increase substantially toward the older ages and longer terms of service, the average cost for all employees combined will remain practically constant provided the present distribution by age and term of service is maintained throughout the future.

The portion of the total pension liability assigned to each year of service may be measured by the relative cost per dollar of pension purchased in the respective years. On this basis a relatively small portion of the liability is assigned to the earlier years of service, while the major portion is assigned to the later years of service immediately preceding retirement. This is true not only on an employee basis but also on a salary basis.

The cost of individual annuities increases with the advancing age and term of service. As the employee grows older, the time of retirement on pension approaches ever nearer and naturally the single premium per unit of pension purchased increases for both the employee and the employer. The employee's contribution, however, remains a level percentage of his salary, so that the entire increase in cost is borne by the employer, thereby accentuating the increasing trend of the employer's cost. From another point of view, the employee's level contribution will, because of his advancing age, purchase a decreasing portion of the total deferred annuity purchased each year. This leaves an increasing portion to be purchased by the employer. The increasing trend in the cost is, therefore, relatively greater than it would be if the entire cost were borne by the employer.

Another factor influencing the trend in the employer's cost is the rate of withdrawal from service. When an employee leaves the service by reason of resignation or dismissal, the accumulated contributions made by the employer are refunded. This reduces the cost otherwise borne by the employer. The interesting point, however, is that this reduction in the cost actually accentuates the increasing trend. The withdrawal credit for each employee leaving the service will, of course, be greater at the longer terms of service. The rate of withdrawal, on the other hand, shows a marked tendency

to decrease with term of service. In most cases, this decrease in the rate of withdrawal is sufficient to counter-balance the increasing credit per withdrawing employee and produces a total withdrawal credit which, when expressed as a percentage of the cost otherwise borne by the employer, actually decreased with the term of service.

Summarizing, we find that each of the following three factors cause the employer's cost to increase either with the advancing age of the employee or with the advancing term of service:

1. The single premium per unit of deferred annuity purchased increases with advancing age.
2. The employee's level percentage contribution purchases a decreasing portion of the total annuity purchased each year leaving an increasing portion to be purchased by the employer.
3. The withdrawal credit, when expressed as a percentage of the cost otherwise borne by the employer, usually decreases with the term of service.

The employer should be fully informed not only as to the current cost for the first year the plan is in operation, but also as to the probable cost ten, twenty and thirty years hence. Detailed computations should be made to determine the probable future trend in the cost expressed as a percentage of the payroll. As already explained, the method produces costs which are relatively low at the younger ages and at the shorter terms of service, but which increase to a marked extent toward the older ages and longer terms of service. The aggregate cost for all employees combined depends, therefore, on the distribution of the employees according to age and term of service. As the particular business grows older and more stabilized there is an inevitable shift in the employees to the older ages and longer terms of service. Under these conditions the future cost, expressed as a percentage of the total payroll, will increase steadily for a long period of years before tending to stabilize. In some typical instances detailed computations indicate that the average percentage cost for all employees combined will eventually reach a figure more than double the initial cost.

The insistence that new employees be hired at the younger ages to the exclusion of the applicant over forty or forty-five, is, at best, only a temporary expedient. In periods of rapid expansion it may, for a time, be possible to hire younger employees in sufficient numbers even to reduce the average age and term of service of the entire group. To continue such a program indefinitely, however, would mean not only an ever increasing number of new employees each year but also in many cases an ever increasing rate of growth in the total number of employees and possibly a further reduction in the maximum hiring age.

Such computations of the probable future trend in the cost necessarily involve both the rate of increase in salary and the rate of termination of service by withdrawal. Neither of these factors may be determined with that high degree of preciseness which may be attained when dealing with mortality rates. Even though there is the inherent risk of finding that the future experience differs from the assumed rates by as much as twenty or

twenty-five per cent it is preferable to determine these factors on the basis of the past experience of the particular group with suitable adjustments in the light of changed conditions rather than err one hundred per cent by ignoring them entirely. The insurance companies can not, of course, go so far as to guarantee to the employer that the actual increase in cost will be within the estimates submitted in advance.

Financed by Level Percentages of Payroll. This method approaches the problem from the point of view of establishing a control over the trend in pension costs on a basis whereby costs are maintained at an equable load from year to year under varying business conditions. With the continued growth of the company, or more so, for variations in its growth there will be for many years a pronounced change in the distribution of employees by term of service. Accordingly, the cost of the benefits promised is evenly distributed throughout active service as a level percentage of salary. By thus establishing the pension costs independent of term of service, we are enabled to maintain the future costs at an even percentage of future payroll under wide variations in the growth of the company.

As regards the distribution according to age at employment, there is usually a slight tendency of a shift toward the younger ages at employment. This can have but little effect on the average cost for all ages at employment combined, however, since the level percentage cost for most plans will vary little from the younger ages at employment to the older ages. The somewhat wide variation frequently shown is more apparent than real in that it arises from the particular method of computation usually adopted. The method in question involves the construction of a single set of basic tables based on attained age only, whereas the more scientific but laborious method involves the construction of several such sets of basic tables for selected ages at employment. While such a short-cut method can be made to produce substantially accurate results for all ages at employment combined, it fails utterly to produce accurate results for individual ages at employment. The method understates the cost for the younger ages and overstates the cost for the older ages.

Incidentally, the more laborious computations for selected ages at employment show that industrial employees entering the service between ages 40 and 50 or even 55 can be provided with quite substantial pension benefits without any material increase in the average cost. There is, therefore, no real justification for the common practice of refusing to consider applicants over 40 or 50 on the mere grounds that the pension costs will be unduly increased by the inclusion of such applicants.

The level percentage method definitely recognizes in advance that a large proportion of the employees will leave the service and hence will never be retired on pension. The cost is computed on the basis that when an employee does leave the service, the employer's accumulated contributions shall remain in the fund. Consequently there is no refund to the employer in the nature of a withdrawal credit as is the case under either the single premium or annual premium group methods commonly employed when the plan is reinsured. The reduction in the cost by reason of withdrawals is reflected directly in the level percentage figure.

One objection frequently made to the level percentage method is that the continued application of a predetermined percentage may result in a material accumulation of errors over a period of years. This objectionable feature may be avoided, however, by making annual revaluations of the pension liability and then computing the annual cost as the amount required to maintain the accumulated funds in line with the computed liabilities. The annual cost would be obtained as follows:

Add:

1. The increase in the pension liability during the year as disclosed by the annual revaluation.
2. Pension payments made during the year to disabled and retired employees.

Deduct:

1. Interest earned during the year on the portion of the pension liability already funded.
2. Interest at . . . per cent for the year on the portion of the pension liability *not* then funded. (The rate of interest which should be used for this item is the rate assumed in the construction of the valuation factors and percentage cost factors.)

The annual cost computed in the above manner may be said to represent the *actual* pension costs in respect of service rendered during the year. The predetermined percentage cost, on the other hand, may be said to represent the *expected* pension costs. This is what the *actual* cost would be if the experience of the pension plan as regards withdrawals, mortality, retirements, salary increases, etc., were always in exact agreement with the fundamental factors adopted. Any wide divergence between the *actual* cost and the *expected* cost will indicate that the experience of the pension plan during the particular year is not in sufficiently close agreement with one or more of the fundamental factors. A further study should then be made to determine which factors are out of line and whether the lack of agreement is due to some cause peculiar to the particular year or to some cause which is likely to be present in the future to an extent sufficient to warrant adjustments in the valuation factors and percentage cost factors.

The *actual* cost by the above method is not disclosed until some time after the end of the year when the annual revaluation is completed. It is frequently desirable, however, to know the pension costs in advance and month by month, especially if monthly statements are being compiled. The *expected* cost based on the predetermined percentages is of value at this point in that it indicates in advance the probable pension costs. The necessary adjustment in the pension costs is then disclosed by the valuation as of the end of the year and may be financed as follows:

1. The adjustment may be absorbed immediately in one sum, or
2. The adjustment may be spread evenly over the following twelve months,

or

3. If the adjustment is unusually large because of accidental variations in the actual experience as regards withdrawals, mortality, retirements, salary increases, et cetera, the adjustment may be spread over a period of years and financed as a part of the initial pension liability still remaining to be funded.

Financed by Annual Premium Group Annuities. This method is still occasionally adopted when a pension plan is reinsured. It differs from the single premium group annuity method in that it produces a larger accrued liability and a pension cost which decreases with term of service instead of increasing. Under this method a deferred annuity based on the current salary and the number of years which will have been served upon the attainment of a designated retirement age is purchased by means of level annual premiums payable until the retirement age. As the salary increases, additional annual premium annuities are purchased at the attained age with the amount of the additional annuity based on the increase in salary and the number of years still remaining to the retirement age. When the employee leaves the service by reason of resignation or dismissal, the accumulated contributions are refunded to the employer as a withdrawal credit.

It should be noted that the basic cost under this method is a level annual premium, and hence the full amount of any dividends or withdrawal credits is applied toward producing a cost which will be lower than the indicated initial cost. The situation is much different from that under the single premium group annuity method where the basic cost is of an increasing nature.

The method has seldom proved to be popular with the employer, because of the relatively large accrued liability and the relatively high initial cost. Nor has he been greatly encouraged by the assurance that pension costs in the future would, by reason of dividends and withdrawal credits, be less than the indicated initial cost.

Financed at Appointment to Service. This method, while not so ambitious as the permanently endowed plan, does place on a rapidly growing industry an unnecessarily severe financial strain at the very time when funds are most needed for expansion purposes. The method undertakes to finance each year the entire pension liability in respect of all employees entering the service during that year. In order to avoid the gradual development of embarrassing situations, it is extremely important under this method that the pension liability be revalued yearly so that frequent minor adjustments may be made in the accumulated reserve fund. The method is defective, however, in that the pension liability for a particular group of employees is not financed out of corporate earnings produced by their own services, but rather out of corporate earnings produced long before by other employees.

Summary

1. Under any method of financing a pension plan, the employer should consider the entire liability assumed; not only the portion recognized by the particular method adopted as already having accrued by reason of past service, but also, what is sometimes even more important, the portion which remains to be incurred during the years to come.

2. The methods which have at one time or another been employed for financing the benefits promised differ chiefly in accordance with the concept of just when the pension liability is actually incurred and hence what portion of the total liability has already accrued by reason of past service.

3. Some of the more usual concepts of when the liability is actually incurred are reflected in the following methods of financing the benefits:

- a. Financed on a *cash disbursement* basis.
- b. Financed at *retirement* on pension.
- c. Financed by *single* premium group annuities.
- d. Financed by *level* percentage of payroll.
- e. Financed by *annual* premium group annuities.
- f. Financed at *appointment* to service.
- g. Financed as a *permanently endowed* plan.

The method usually adopted in the case of a reinsured pension plan is the single premium group annuity method. In the case of the industrial plan which is not reinsured, the level percentage of payroll method is the recognized standard of solvency.

4. The single premium group annuity method of financing approaches the problem of the liability incurred each year as follows: It first assumes that the pension earned during each year of service is proportional to the salary received in that year. It then considers the liability actually incurred during the year as being equal to the single payment required to finance the pension thus earned. The method entirely ignores the resulting trend in pension costs expressed as a percentage of the payroll.

5. The level percentage of payroll method of financing approaches the problem of the liability incurred each year from the point of view of establishing a control whereby pension costs may be maintained at an equable load from year to year under wide variations in the growth of the company. It considers the liability incurred in each year of service as being basically proportional to the salary earned in that year and hence expresses the expected cost as a level percentage of the salary. The actual cost is then computed as the amount required to maintain the accumulated assets in line with the accrued liability as disclosed by annual revaluations. The actual cost should depart from the expected cost only to the extent that the experience as regards withdrawals, etc., during the particular year departs from the assumed factors.

6. Some concepts of just when the pension liability should be incurred produce pension costs which when expressed as a percentage of the payroll show a distinct tendency to increase from year to year. Others produce costs which show a marked trend downward. Then there is one which is designed primarily to produce costs which will as nearly as possible remain a level percentage of the payroll under wide variations in the growth of the company.

7. Where pension costs for one reason or another show a distinct tendency to increase or decrease from year to year, the employer should be fully informed as to the probable future trend in the cost under the particular method of financing adopted.

8. The computations of the future trend in cost to be expected should involve all pertinent factors including the rate of withdrawal from service, the probable future increases in salary, the rate of retirement on pension and the rate of future growth where the particular method adopted is such that future costs will be affected by the growth of the company.

FINANCING PENSION PLANS

BY JOSEPH H. WOODWARD, *Consulting Actuary, Woodward, Fondiller and Ryan, together with introductory comment* BY GILBERT E. AULT, *Associate Actuary of that firm*

Introductory Comment. The application of formulae and tables to a specific problem without full knowledge of the underlying assumptions involved is usually fraught with danger and quite frequently produces results so far off the mark as to be of no value whatever. Pension problems run true to form in this respect. It seems advisable, therefore, to preface Mr. Woodward's article on "Financing Pension Plans" with a word of caution and to point out briefly some of the pitfalls to be avoided.

The formulae and resulting tables in Mr. Woodward's article are based primarily on attained ages in order to reduce to a reasonable basis the otherwise extensive numerical computations when applied to smaller groups of employees. While certain important factors which affect pension costs and pension liabilities depend almost entirely on the attained age of the employee, there are other equally important factors which depend more on term of service. In most cases, however, these factors can be transposed to an attained-age basis without vitiating the final results to any appreciable extent. The salary scale and rate of withdrawal, for example, depend more on term of service than on attained age and for most groups of employees can be analyzed satisfactorily only on a term-of-service basis for selected age-at-employment groups, preferably five year age groups. The transition from a term-of-service basis for each age-at-employment group to an attained-age basis for all ages at employment combined requires due regard for the age-at-employment distribution of the particular group of employees and often taxes the skill of experienced actuaries.

Where the number of employees involved is sufficiently large to warrant the greater expense entailed, it is usually advisable to make separate computations for each age-at-employment group, at the same time distinguishing between male and female employees. Such a procedure naturally increases the numerical computations several fold. At the same time, however, it eliminates entirely the need for the above mentioned transition from factors on a term-of-service basis to an attained-age basis and produces correspondingly more dependable final results. The necessary modifications in the formulae given on the attained-age basis in order to obtain formulae on the term-of-service basis are quite simple and may readily be made when one once understands the basic development of the formulae given.

Another point to be noted is that while the shorter method may be relied upon to give satisfactory results in the aggregate, it is only in relatively few cases that the method produces satisfactory results for component parts of the whole. More specifically, the method when properly applied to a particular group of employees will produce dependable pension costs for all employees combined, but at the same time greatly understates the pension costs for those entering the service at the younger ages and correspondingly overstates the pension costs for those entering at the older ages. This peculiarity of the

method has to a great extent been responsible for the erroneous belief that those entering service at the older ages represent an undue proportion of the total pension costs and should therefore be excluded if aggregate costs are to be kept at a reasonable level. For purposes of illustration, Table II_a shows that on the basis of the so-called "high rate of withdrawal" the pension cost for retirement at age 65 increases from 21 cents per \$1,000 of salary for age at employment 15, to \$2.09 for age at employment 25, to \$12.69 for age 35, to \$36.30 for age 45 and to \$51.83 for age 50. Table II shows the corresponding pension costs on the basis of the so-called "low rate of withdrawal" to be \$4.11, \$10.00, \$22.12, \$41.10 and \$54.19 respectively. Even on the basis of low rate of withdrawal the increase is more than 10 fold. When, however, computations are based on a term-of-service basis for each age-at-employment group, we often find that for male employees the pension cost for the older ages at employment is actually less than the cost for those entering at the younger ages. In the case of female employees where withdrawal rates are decidedly high at the marriageable ages, pension costs may show an increase of from 2 to 3 fold but nowhere near the 10 fold shown by the shorter method under the low rate of withdrawal. The increased cost at the older ages for females however is usually only slightly higher than that for male employees entering at the same age. This represents the net result of a younger retirement age and a lower rate of mortality among female pensioners partially offset by a higher withdrawal rate and a less steep salary curve for female employees, as compared with the corresponding factors for males. In one particular instance, for example, the pension costs for male employees were \$31.72, \$29.95 and \$28.47 per \$1,000 of annual salary for ages at employment 20, 30 and 45 respectively, a slight though definite decrease toward the older ages at employment. The corresponding pension costs for female employees were \$10.68, \$20.46 and \$30.98.

One further point to be borne in mind when considering pension costs is the payroll savings effected through the elimination by retirement of older inefficient employees. In the absence of a pension plan many employees for one reason or another are retained on the payroll long after their period of usefulness to the company and to that extent a portion of their salary constitutes a definite pension cost even though concealed in the regular payroll.

It is at this stage that management itself plays the most important part in the pension program. It is a problem of management to determine when and on what basis employees should be retired. Otherwise the pension plan may on the one hand be ineffective in weeding out older inefficient employees and on the other hand result in the retirement of many employees fully capable of rendering further periods of profitable service to the company. In either case aggregate pension costs will be unnecessarily high. Beyond a certain point any apparent reduction in pension costs under a too restricted scale of benefits will be more than offset by increased pension costs concealed in the regular payroll. Management can in many cases accomplish much toward the reduction of concealed pension costs by a carefully worked out program of retraining older employees and transferring them to work at which they may be continued in service for longer periods with reasonable profit to the company. To this extent the burden on the pension plan can be relieved

and aggregate pension costs including concealed pension costs as well as direct pension costs will be reduced.

This paper describes certain methods of computing the cost and calculating the necessary reserves to be set aside by the employer in connection with the usual type of non-contributory, non-contractual pension plans. In order to limit its scope no consideration is given to any questions of social and economic theory, nor does it attempt to deal with the contributory types of pension plans more often found in connection with groups of public employees or with the employees of financial institutions.

Characteristics of Existing Plans. The National Industrial Conference Board in its recent publication on industrial pensions¹ gives an analysis of 248 plans. Of these, 211 are non-contractual and non-contributory. Of the 211 non-contractual plans, 43 are of what is known as the limited contractual type; that is, a pension having been once granted may not be arbitrarily revoked or reduced. The non-contributory, non-contractual type of plan is thus seen to prevail by an overwhelming majority, and it is to this type that exclusive consideration is given in this paper.

The annual pension payable upon retirement is in nearly all cases a flat percentage—usually 1 or 2 per cent—of the "final salary" multiplied by the number of years of service. The final salary is usually defined as the average salary for the final ten years of service, although the final five years is in many cases specified. In a small minority of cases a percentage of the "total" salary for all years of service is granted which, as may readily be seen, is the same thing as a percentage of the "average salary" multiplied by the number of years of service. In rare cases a flat amount, such as \$40 per month, may be the benefit; or a flat percentage of the final salary, such as 50 per cent. The most usual pensionable age is sixty-five for men and fifty-five for women and at least twenty years of service are commonly required to establish eligibility to a service pension. A pension payable on the occurrence of permanent disability is often provided, usually after fifteen years of service. A death benefit is sometimes provided in the plan itself, sometimes through group insurance and sometimes through an employees' mutual benefit association. Ordinarily there are provisions for maximum and minimum limits for the benefit payable.

How Pension Plans Develop. During the early years of an industrial enterprise, very few employees become superannuated. With the lapse of time, however, the necessity arises for replacing the older employees with younger men.

As the pension list grows a formal system of rules governing the granting of pensions naturally comes into being. In formulating these rules, the rules of other industrial concerns are usually taken as a guide, special regard being had for enterprises in the same line of business, more especially if they happen to be so situated that they compete for employees in the same labor market. The final step in the development of pension plans is the realization

¹"Industrial Pensions in the United States," National Industrial Conference Board, New York, 1925.

that, unless properly financed, these plans involve an increasingly heavy financial burden.

This leads to a demand for financing upon an actuarial basis, a demand which has been further stimulated by recent contributions of life insurance companies to the solution of the pension problem by means of the issue, under a group arrangement, of various forms of savings or deferred annuity contracts.

Costs and Reserves. When an employer decides to determine actuarially the position of a pension system, he first asks two questions:

1. How much does the system cost?
2. How much are the liabilities assumed?

It is necessary to consider very carefully just what these questions mean.

How much should the accounts of the employer show as the true cost of the pension plan for any particular calendar year?

Let us start with the definition that the cost of a pension in the case of any particular employee is that level percentage of his salary which, accumulated at interest during his entire period of active service, will, taking into account the probabilities of death, disability, withdrawal from service and increase in salary, be exactly sufficient on the average to provide for a pension according to the rules.

When an employee leaves the service prior to retirement the fund accumulated for his benefit is, so to speak, "forfeited" for the benefit of those who remain in the service up to the pensionable age. Since only a very small percentage of employees spend all or most of their active life in the service of one employer it follows that the cost of a plan providing no withdrawal benefits is much less than the cost of a plan which permits withdrawing employees to take with them accumulations set aside on their behalf. It is, in fact, this great difference in the cost which is the principal obstacle to the adoption of contributory plans, since under a contributory plan equity requires that the contributions of the employee, with interest, should be returned to him on withdrawal from service.

Rarely, if ever, is provision for future pensions made at the starting of a new enterprise. For that reason it is necessary, at the time when the pension plan is first placed upon an actuarial basis, to find some method of dealing with the benefit which has accrued by reason of service rendered prior to the date of inception or reorganization of the plan. The actuarial liability on account of such service is defined as the "accrued liability."

The best method of dealing with this situation is to first compute the "normal cost" on the assumption that this normal cost has been set aside each year in the past since the date of entry into employment. The normal cost, as respects any employee, accumulated with benefit of survival in service up to the date of inception or reorganization of the plan, is then the accrued liability in respect of such employee.

The following table shows the normal cost for quinquennial ages at entry into service calculated on the assumption of a relatively low rate of withdrawal.

1358 HANDBOOK OF BUSINESS ADMINISTRATION

NORMAL ANNUAL COST PER \$1,000 OF ANNUAL SALARY FOR ACTIVE EMPLOYEES

Pension at age 65 of 1 per cent of salary times years of service, interest, 4 per cent

Age at entry into service	Normal annual cost ¹
15	\$ 4.11
20	6.40
25	10.00
30	15.21
35	22.12
40	30.70

¹ As explained later, for a given employee the first payment of the normal cost is assumed to be made after the employee has been in the service two years.

Recently several of the larger insurance companies have become interested in the financing of pension plans. The general method they have followed is to sell to the employer a deferred annuity for each employee, such annuity to begin at the retirement age and to be for an amount determined according to certain rules stipulated in the original contract between the employer and the insurance company.

Where, however, the plan is "self-insured," the following table illustrates the reserves, calculated on the same basis as the normal costs previously given, required to be set up in respect to an employee who entered the service at age twenty.

AGE AT ENTRY INTO SERVICE, 20 YEARS	
Normal Annual Cost \$6.40 per \$1,000 of annual salary	
Number of years of service ¹	Reserve per \$1,000 of annual salary at end of indicated number of years of service
$\frac{1}{2}$	0
$1\frac{1}{2}$	0
$2\frac{1}{2}$	3
$3\frac{1}{2}$	11
$4\frac{1}{2}$	19
$14\frac{1}{2}$	182
$24\frac{1}{2}$	634
$34\frac{1}{2}$	1,567
$44\frac{1}{2}$	3,665

¹ It is assumed that an employee on the average enters service on June 30; hence at the date when valuations are generally made, Dec. 31, an employee has on the average one-half year of service to his credit for the first calendar year; one and one-half years of service for the next calendar year, etc. That is why reserves are given for half-years of service.

From the above table it is seen that for the first and second calendar years no reserve is set up but that at the end of the third calendar year of service a

reserve of \$3 is required for each \$1,000 of average salary during the past year. Similarly, at the end of the fourth calendar year \$11 per \$1,000 of average salary during that year should be on hand, etc., until the end of the forty-fifth year, when \$3,665 per \$1,000 of average salary is called for. This amount is calculated as sufficient to "purchase" the pension which under the rules would then be entered upon.

By applying a similar procedure to all employees the aggregate reserve may be readily calculated.

Due to the wide divergencies of withdrawal rates as between different enterprises it is indispensable that a separate investigation be made of the past experience of the individual enterprise whose pension plan is to be valued. Where it is impracticable to make such an investigation, either because the concern is new or because it has not kept employment records with the necessary details, or because it is unwilling to go to the necessary expense, then it is necessary to assume rates of withdrawal which appear conservative under the circumstances. From four to six years is usually a sufficient period to be covered in the investigation of experience.

For valuation purposes, whether the past experience is to be investigated or not, cards must in any event be written or punched for every active employee in service on the valuation date showing (1) year of birth, (2) date of entry into employment, (3) salary, and (4) sex, together with the particulars necessary for identification. Where the rate of withdrawal is to be investigated cards must also be punched or written for every employee whose service was terminated for any reason whatever during the period covered by the investigation showing (1) year of birth, (2) date of entry into employment, (3) date of termination of employment, (4) sex, and (5) mode of termination of employment (whether by withdrawal, death, disability, or retirement on pension).

Exposed to Risk. When an employee once enters upon a given year of service at a given age he is said to be "exposed to risk" for that year and for that age.

In calculating the exposed to risk an important point to be considered is the extent to which the data should be investigated by length of service in addition to age attained. Rates of withdrawal for any particular age are greatly affected by duration of service, even when the first two or three years of service are excluded.

In order to reduce the fluctuations arising from labor turnover and to eliminate from consideration employees whose connection with the company is hardly more than casual, a convenient device is to exclude the first two or three years of service and to assume that no accumulation of normal cost is to be commenced in respect to any employee until he has completed this preliminary term. By using this device, over 75 per cent of the labor turnover is eliminated entirely, and the investigation is confined to those employees who are most likely to remain in the service permanently.

After the exposed to risk has been computed for various ages the next step is the determination of the rates of withdrawal, mortality and disability. The number of withdrawals at age 20 during the period of the investigation may be represented by the symbol w_{20} , deaths by d_{20} and disabilities by r_{20} .

1360 HANDBOOK OF BUSINESS ADMINISTRATION

To illustrate, assume that of 240 employees who completed their second year of service at age twenty, 30 withdraw during the third year of service. The rate of withdrawal at age twenty would then be defined as $\frac{30}{240} = 0.125$ per employee, or 125 per 1,000. Rates of mortality and disability are calculated in a similar manner using the actual number of deaths or cases of disability.

Unless the experience is very large the crude rates will be irregular and it is the practice to smooth them out or, as is technically termed, "graduate" them into a smooth series.

Rate of Withdrawal. The rate of withdrawal takes account of discontinuances for all causes except death, retirement on pension and permanent disability. Withdrawals fall into two classes: voluntary and involuntary. The voluntary group includes employees who leave the employment to seek altered or better working conditions. The involuntary group includes employees who have been laid off by reason of business depression. Where employees are involuntarily laid off in large numbers and the rules provide that, on return to work, credit will be given for prior service rendered, there may be considerable undisclosed liability for past service in connection with valuations made at the low point of an employment cycle.

For purposes of comparison the following graduated rates of withdrawal (excluding either the first two or the first three years of service) are given for decennial ages upon the basis of four different industrial experiences:

RATE OF WITHDRAWAL PER 1,000

Age	Company A	Company B	Company C	Company D
20	125	201	169	250
30	110	151	121	222
40	73	126	77	140
50	31	83	42	64
60	4	36	16	25

The differences in these rates are rather formidable and indicate what a wide range of conditions is likely to be met with. In the case of companies A, B, and C the rates are based on experience with the first two years of service excluded. In the case of company D the first three years of service were excluded.

The Rate of Mortality. Save where a very large experience can be investigated there is but little to be learned from the experience as to the probable mortality among pensioners or active employees. Except at the higher ages, however, rates of mortality have little effect, relative to other factors, on the cost of the pension benefit. Unless some special occupational hazard is present, the rates of mortality taken from a standard table, such as the American Men Ultimate Mortality Table, will be satisfactory. The following table illustrates these rates of mortality for decennial ages:

RATE OF MORTALITY PER 1,000
AMERICAN MEN ULTIMATE TABLE OF MORTALITY

Age	Number of deaths to be expected in one year per 1,000 employees at age given
20	3
30	4
40	6
50	12
60	27
70	61
80	136

The Rate of Disability. Due to the many interpretations that may be given to the term "total disability," it is difficult to come to any definite conclusions as to what rate of disability is likely to be experienced among a given group of industrial employees.

The rate of mortality among pensioners actually receiving a disability annuity is another troublesome point due largely to the difficulty in obtaining a sufficient exposed to risk. What we are really interested in in such cases is, of course, the total rate of termination of the benefit from both death and recovery. For practical purposes it is sufficiently accurate to use a standard disability table "loaded" to meet the conditions in the particular case.

Salary Scale. A salary scale may be defined as the ratio of the average salary at any age to the average salary at some specified age taken as a base.

The general characteristics of an industrial salary scale are a rapid increase at the younger ages, a slower increase at the middle ages and a comparatively stable salary for several years preceding the pension age. Due to the fact that in most pension plans the benefit depends on a percentage of the final salary, it is important to avoid too low a scale at the higher ages. A convenient method of expressing the salary scale is to express all salaries in terms of a salary of \$1,000 at age sixty-five. For example, if experience showed the average actual salary at age sixty-five to be \$2,100 and employees at age twenty-five received on the average \$1,050, then the salary scale would show a relative salary at age twenty-five of \$500.

For purposes of comparison the graduated salary scales for quinquennial ages are shown on page 1362, based upon the experience of the same four industrial enterprises for which rates of withdrawal have been previously given.

In general it will be found that the salary scale is not so much affected by duration of service as is the rate of withdrawal and it is doubtful whether, under ordinary conditions, it is worth while to investigate the salary by durations.

Most pension plans contain a provision for a maximum benefit, and in constructing the salary scale it is necessary to eliminate excesses of salary over amounts on which a pension benefit would be based. Care should also be

taken to provide uniform and consistent instructions as regards the conversion of daily or weekly wages into annual rates.

SALARY SCALE
(Per \$1,000 at age 65)

Age	Company A	Company B	Company C	Company D
15	\$ 170	\$ 210	\$ 220	\$ 380
20	370	570	340	500
25	550	780	480	670
30	720	900	630	770
35	850	960	760	820
40	930	980	870	860
45	960	1,000	940	880
50	980	1,000	980	910
55	990	1,000	1,000	970
60	1,000	1,000	1,000	1,000
65	1,000	1,000	1,000	1,000

Service Table. A service table in its relation to pension fund finance is analogous to a mortality table in relation to life insurance finance. A service table is like a mortality table except that it includes in addition to the mortality element the elements of withdrawal and disability. The salary scale is also usually considered as a part of the service table.

After the rates of withdrawal, mortality and disability, have been determined, the service table is constructed somewhat as follows: At a certain age of completion of the first two years of service, say fifteen, an arbitrary number of active employees—called the “radix” of the table—is assumed, say 10,000,000. Using Table I at the end of this article for illustration, we see that at age fifteen 128,769 will withdraw, 3,460 will die and 1,018 will become disabled per each 1,000 of employees aged fifteen. Hence for 10,000,000 we shall have 1,287,690 withdrawing, 34,600 dying and 10,180 disabled, or a total number of separations from active service at age 15 of 1,332,470. Subtracting this latter figure from 10,000,000 leaves 8,667,530 of the original 10,000,000 employees who will “survive” to age sixteen. This process is carried forward from year to year until at age seventy, 75,907 employees would, under the assumptions as to withdrawal, mortality and disability, survive in active service. The column showing how many employees are in active service at a given age x is usually termed the l_x column. For example, $l_{15} = 10,000,000$ and $l_{60} = 227,848$ in the specific table we have been using as an illustration. To find from our table how many employees would be in active service at age fifty where 3,270 for example had completed two years of service at age fifteen, it would only be necessary to multiply 3,270 by 227,848/10,000,000 giving seventy-five employees as the answer to the question.

Salary scales and rates of withdrawal show characteristic differences for male and female employees. Hence, where a large proportion of the employees are females it is essential that separate consideration be given the sexes throughout the investigation. This, however, doubles a large portion of the work, so that when the females are not many in number or when the element of expense has to be considered, the experience of both sexes may be combined and the results used to construct the service table without any great loss in accuracy. Most pension plans allow younger retirement ages for females than for males, and it is necessary in any event that this fact be given consideration in computing normal costs and reserves.

Age at Retirement. Employees are seldom retired at the specified retirement age, more especially where the retirement privilege is optional. A liberal pension benefit and low retirement age tend to increase the extent to which optional benefits are availed of. On the contrary, small pensions and a high pension age tend to increase the actual retirement age. The existence of a large group of employees with thirty or forty years of service to their credit would tend to reduce the average age at retirement.

By averaging the ages at which pensions have been granted in the past an average actual retirement age may be ascertained and pension costs computed on the basis that employees will be retired at that age. A more conservative method is to assume that all employees attaining the optional age will become pensioners at that age.

Formulae for Normal Costs and Reserves. The following is a brief description and explanation of the formulae for normal costs and reserves.

A formula for the normal cost expressed as a level percentage of the salary payable from age x (where $x - 2$ is the age at entry into service) of a pension at age sixty-five of 1 per cent of the final salary multiplied by the number of years of service, may be stated as follows:

$$100 {}^{65}P_{[x-2]+2} = \frac{s_{65} (65 - \overline{x-2}) \bar{a}_{65} v^{65-x} \frac{l_{65}}{l_x}}{.01 s_x {}^s\bar{a}_{x:65-x}|} \quad (1)$$

where

$100 {}^{65}P_{[x-2]+2}$ = normal cost expressed as a level percentage of annual salary.

s_{65} = Scale salary at age 65.

s_x = Scale salary at age x .

$[x-2]$ = Age at entry into service.

x or $[x-2]+2$ = Age two years after entry into service at which payments of normal cost begin.

\bar{a}_{65} = Present worth at age 65 of an annuity of \$1 per year, payable in monthly installments until death.

v^{65-x} = The compound discount factor to discount \$1 from pension age 65, to present age x . If rate of interest is 4 per cent v^{65-x} would equal $(1/1.04)^{65-x}$

l_{65}/l_x = Probability that a given employee aged x will be eligible for a pension at age 65.

$65 - \overline{x - 2}$ = Number of years of past service rendered when employee has reached age 65.

${}^{\bar{a}}_{x:65-x}$ = Present worth at age x of an annuity payable in monthly installments until age 65 or until premature termination of service for any reason whatsoever, equal in amount to \$1 the first year and increasing year by year in proportion to salary to be received as indicated by the service table.

Assume for purposes of illustration that the employee receives and will receive in the future, salaries as actually expressed in the salary scale, i.e., s_{65} at age 65, s_x at age x , etc. The number of years of service rendered at age 65 will be $65 - (x - 2)$, i.e., the number of years between age at entry and age at retirement; 1 per cent of salary at age 65 will be $s_{65}/100$ and by definition the yearly pension to be received will be $\frac{s_{65}}{100}(65 - \overline{x - 2})$. As this amount will be paid as an annuity at age 65, its value at age 65 is itself times \bar{a}_{65} , the present value of an annuity of 1 at age 65. Thus the value of the benefit at age 65 is $\frac{s_{65}}{100}(65 - \overline{x - 2}) \bar{a}_{65}$. But what we are interested in is the *present* value of the benefit as respects any given employee.

As there are l_x employees at age x and l_{65} at age 65, the probability that a given employee aged x will be one of the l_{65} at age 65 is l_{65}/l_x ; hence his chance of receiving the pension benefit at age 65 is l_{65}/l_x . The chance of receiving the benefit at age 65, multiplied by the value of the benefit at age 65 gives the present value sought after interest has been taken into account by multiplying the result by v^{65-x} . Hence the present value of the benefit for any employee at age x and receiving a salary of s_x is $\frac{s_{65}}{100}(65 - \overline{x - 2}) \bar{a}_{65} \frac{l_{65}}{l_x} v^{65-x}$.

The factor $.01 s_x {}^{\bar{a}}_{x:65-x}$ in formula (1) represents the present value of an annuity of 1 per cent of the employee's salary, beginning with a salary of s_x at age x . Hence, if this is the present value of 1 per cent of salary, to find out what percentage of future salary must be taken to amount to the benefit it is only necessary to divide the present value of the benefit by the present value of 1 per cent of future salary. This gives the normal cost.

The reasoning above given may, of course, be readily modified so as to apply to any specified retirement age, or any other initial salary at age x , or to any other percentage of final salary multiplied by number of years of service. Using actuarial notation the following formula (2), equivalent to formula (1), would be the formula actually used in practice.

$$100 {}^6\bar{P}_{[x-2]+2} = \frac{{}^6D_{65}(65 - \overline{x - 2}) \bar{a}_{65}}{{}^6N_x - {}^6N_{65}} \quad (2)$$

Denoting by ${}^6\bar{V}_{[x-2]+2}$ the reserve per unit of salary, at the end of the n th year of service, we may first note that when $n = 1$ or $n = 2$, that is, at the end of the first or second year of service, the reserve is 0. This is

because no normal cost is assumed to be contributed until after two years of service. When $n = 3$, that is, at the end of the third year of service, the reserve may be expressed as follows:

$${}^3_3 \bar{V}_{[x-2]+2} = \frac{{}^8_{65}}{100} (65 - \bar{x} - 2) \bar{a}_{65} \frac{l_{65}}{l_{x+1}} v^{65-(x+1)} - 100 {}^6\bar{P}_{[x-2]+2} (.01) {}^8s_{x+1} {}^8a_{x+1:65-(x+1)} \quad (3)$$

where the symbols have the same meaning as in formula (1) except that in several places the attained age after three years of service ($x + 1$) is substituted for the age after two years of service.

The logic of the above formula may be briefly explained in the following manner. By comparison with the paragraph illustrating the derivation of formula (1) it may be seen that the first half of formula (3) namely

$$\frac{{}^8_{65}}{100} (65 - \bar{x} - 2) \bar{a}_{65} \frac{l_{65}}{l_{x+1}} v^{65-(x+1)}$$

is the present worth to an employee aged ($x + 1$) of a benefit taking account of $(65 - \bar{x} - 2)$ years of service, instead of $(65 - (x + 1) - 2)$ years as would be the case for a new employee aged ($x + 1$) who had entered the service two years ago. If no future contributions were expected this expression would represent the liability, but future contributions are expected amounting to $100 {}^6\bar{P}_{[x-2]+2}$ per cent of future salaries. Hence the present value of these are deducted from the present value of the benefit. The present value of such future contributions is

$$100 {}^6\bar{P}_{[x-2]+2} (.01) {}^8s_{x+1} {}^8a_{x+1:65-(x+1)}$$

Finally, deducting this last factor from the first gives the reserve as shown by formula (3). A similar process is followed for other durations of service. Using commutation columns formula (3) may be expressed as follows:

$${}^3_3 \bar{V}_{[x-2]+2} = \frac{{}^8D_{65} .01 (65 - \bar{x} - 2) \bar{a}_{65}}{{}^8D_{x+1}} - 100 {}^6\bar{P}_{[x-2]+2} \frac{{}^8N_{x+1} - {}^8N_{65}}{{}^8D_{x+1}} \quad (4)$$

and

$${}^n_n \bar{V}_{[x-2]+2} = \frac{{}^8D_{65} .01 (65 - \bar{x} - 2) \bar{a}_{65}}{{}^8D_{x+n-2}} - 100 {}^6\bar{P}_{[x-2]+2} \frac{{}^8N_{x+n-2} - {}^8N_{65}}{{}^8D_{x+n-2}} \quad (5)$$

will give the reserve at the end of n years of service.

$${}^{n+\frac{1}{2}}_{n+\frac{1}{2}} \bar{V}_{[x-2]+2} = \frac{1}{2} \{ {}^n_n \bar{V}_{[x-2]+2} + {}^{n+1}_{n+1} \bar{V}_{[x-2]+2} \} \quad (6)$$

represents the reserve at the end of $n + \frac{1}{2}$ years of service per unit of salary at that time.

If the employees are classified by grouping all those who have entered service during a particular calendar year by age at entry nearest birthday, we may assume that employees enter on the average in the middle of a calendar year at their exact ages, and that an employee aged $x - 2$ will, at the end of the

n th calendar year, where the calendar year of entry is counted as year 0, have served $n + \frac{1}{2}$ years and have attained age $x + n - 1\frac{1}{2}$. Formulae (2) and (5) are based on the assumption of a pension benefit of one per cent of the final salary for each year of service. If the rules provide for a benefit of 2 per cent or any other specified per cent, the corresponding normal costs and reserves may be immediately calculated by multiplying by the ratio which the specified percentage bears to 1 per cent.

High and Low Rates of Withdrawal. To show the effect of the withdrawal rate on costs and reserves the following comparative tables of costs and reserves have been inserted. The high and low withdrawal factors are taken from the tables at the end of this paper, denoted I and Ia respectively.

NORMAL ANNUAL COST PER \$1,000 OF ANNUAL SALARY FOR ACTIVE EMPLOYEES

Pension at age 65 of 1 per cent of salary times years of service,
Interest 4 per cent
(Accumulations to commence with *third* year of service)

Age at entry into service	Normal annual cost for		Ratio of column 3 to column 2
	High rate of withdrawal	Low rate of withdrawal	
1	2	3	4
15	0.21	4.11	19.57
20	0.67	6.40	9.56
25	2.09	10.00	4.78
30	5.69	15.21	2.67
35	12.69	22.12	1.74
40	23.18	30.70	1.32
45	36.30	41.10	1.13
50	51.83	54.19	1.05

From the above table it is seen that the effect on the normal annual cost, of doubling the withdrawal rate, is at entry age fifteen equivalent to multiplying that cost almost twenty-fold. This effect decreases until at the older entry ages such effect is practically negligible due to the smaller number of withdrawals at the higher ages. The normal costs shown above are based on what might be termed average maximum and minimum rates of withdrawal for the general experience to be found in industrial enterprises. It is easily seen that the rate of withdrawal is the dominant factor in determining the cost of these non-contributory plans.

The following table shows the effect of differing withdrawal rates on the reserves:

RESERVES PER \$1,000 OF ANNUAL SALARY FOR ACTIVE EMPLOYEES
Pension at age 65 of 1 per cent of salary times years of service, interest 4 per cent

Years of service $n + \frac{1}{2}$	Reserves at end of $n + \frac{1}{2}$ years of service for indicated ages at entry into service							
	15		25		35		45	
	High rate of withdrawal	Low rate of withdrawal	High rate of withdrawal	Low rate of withdrawal	High rate of withdrawal	Low rate of withdrawal	High rate of withdrawal	Low rate of withdrawal
$2\frac{1}{2}$	0	2	1	5	7	12	19	21
$3\frac{1}{2}$	0	7	4	17	23	36	61	66
$4\frac{1}{2}$	1	12	8	29	42	64	108	115
$9\frac{1}{2}$	5	47	46	121	200	248	421	423
$19\frac{1}{2}$	70	230	378	521	917	917	1,613	1,611
$29\frac{1}{2}$	491	733	1,324	1,362	2,439	2,434		
$39\frac{1}{2}$	1,671	1,763	3,259	3,256				
$49\frac{1}{2}$	4,075	4,074						

This table shows that the effect of the withdrawal rate on the reserves is the greatest for the younger ages at entry and for the shorter durations of service. As the duration of service increases, the reserve values approach each other until at attained age sixty-five they are identical.

Illustrative Tables. Table I is a service table computed on the basis of the following assumptions: withdrawal rates as previously given for company A; salary scale as previously given for company C; American Men Ultimate Mortality; rate of becoming disabled, 200 per cent of Hunter's Disability Table. While these assumptions are somewhat more conservative than would apply to the average industrial enterprise, it is not intended or suggested that the table be used in any actual case, unless a full study of the facts showed its adaptability to the circumstances. It is almost always necessary to construct a special service table to meet individual conditions.

Table Ia is a service table calculated on the assumption that the rate of withdrawal at all ages is twice as great as it was in Table I. Rates of mortality, disability and the salary scale are assumed to be the same as in Table I.

Table II shows the value of $1,000^* \bar{P}_{[x-1]+1}$ computed on the basis of Table I with 4 per cent interest, for the four retirement ages 55, 60, 65, and 70. Normal annual costs for intermediate retirement ages may be approximated by interpolation.

Table IIa shows the value of $1,000^* \bar{P}_{[x-1]+1}$ computed on the basis of the service Table Ia.

Tables III and IIIa give for quinquennial ages at entry and all durations the reserve factors corresponding to the normal annual costs given in Tables II and IIa respectively.

In applying the method of valuation herein described it is necessary to have a schedule showing the salaries of all active employees arranged according to age at entry into service and years of entry into service.

The reserves as of Dec. 31, 1925, for example, might be determined as in the following illustration. The reserve factors are taken from Table III at the end of this paper.

RESERVES FOR ACTIVE EMPLOYEES
In Service Dec. 31, 1925; Retirement Age, 65 years; Year of Entry into Service, 1923; Duration of Service $2\frac{1}{2}$ years

Age at entry group	Number of employees in group	Salary of group during 1925	Reserve per \$1,000 of annual salary	Total reserve Col. 3 x Col. 4 1,000
1	2	3	4	5
13 to 17	2	\$ 1,240.00	\$2.00	\$ 2.48
18 to 22	4	4,370.00	3.00	13.11
23 to 27, etc.	7	10,500.00	5.00	52.50
Totals.....	13	\$16,110.00	\$68.09

Similar schedules would be drawn up for years of entry 1922, 1921, and so on. A grand total of all these schedules would show the reserves which should be on hand in respect of active employees as of the valuation date. The difference between the reserve thus found and that actually in hand would indicate the actuarial deficiency or surplus of the system. If the system shows a deficiency, such deficiency may be gradually extinguished either by setting aside a certain amount each year calculated to wipe out the deficiency after a predetermined number of years or by providing for the setting aside each year of an additional percentage of the pay roll until the deficiency has been liquidated.

The average normal cost for the year would be calculated by multiplying the total present salaries for each age at entry by the proper percentage for that age and taking the total. If this total be divided by the total salaries upon which it is based, the result will give the percentage of the annual pay roll (excluding salaries of employees with less than two years of service) which the pension system is costing. The average normal cost expressed as a percentage of the gross pay roll may be found by dividing the total normal cost as above computed by the gross annual pay roll.

The Valuation of Pensions in Force. Pensions which have been granted and are in force may be valued as continuous or monthly annuities. In Table IV is given the present worth at the attained age of the pensioner of \$100 per year payable in monthly installments, for both service pensioners and for disability pensioners.

Advantages of Tabular Reserves. A scheme of tabular reserves as just described has certain advantages, all of which may not be obvious at first sight.

After the normal costs and reserve tables have once been calculated, the method is easy to apply and the employer may make a yearly valuation without actuarial assistance although every five or six years a recomputation of the basic tables based upon the company's intervening experience should be made by an actuary.

Further, the employer can tell just how much he is setting aside as respects any given employee, and how much the reserve as respects any employee is.

By making a valuation each year the employer may readily keep account of the progress which is being made in the extinguishment of the accrued liability. During prosperous years he may desire to set aside a large amount toward the amortization of the accrued liability, while in lean years he may desire to set aside only the minimum amount necessary to avoid any increase in the deficiency of the system.

TABLE I.—SERVICE TABLE BASED ON LOW RATE OF WITHDRAWAL

Attained age	Rate of termination of service per 1,000 (excluding first 2 years of service)			Of 10,000,000 employees entering pension plan at age 15 after 2 years of service					Salary scale	Attained age
	By withdrawal	By death	By disability	Number in service at attained age x	Number of terminations of service between ages x and $x + 1$				Salary at age x corresponding to a salary of \$1,000 at age 65	
					By withdrawal	By death	By disability	Total decrement		
x	$1,000q_x^w$	$1,000q_x^d$	$1,000q_x^r$	L_x	w_x	d_x	r_x	$w_x + d_x + r_x$	$1,000s_x$	x
